During the Late or Terminal A-Group (ca. 3200–2900 BC), the core area of this culture did not change. Contacts were still present with Predynastic sites to the north, while more elusive, though present, were contacts with the Middle Pre-Kerma culture (Honegger 2006). Sites and cemeteries are unknown in Upper Nubia during the fourth millennium BC, while a cultural phase named in the area as Pre-Kerma is known at Kerma (Sites 1, 27 and 21), covering a period from 3100 to 2500 BC (Honegger 2004: Fig. 5 Middle Pre-Kerma, and Fig. 6 Late Pre-Kerma). Pre-Kerma pottery is also known from sites north of the Third Cataract, at Sai Island, at the Arduan Islands, and in the area of the Fourth Cataract.

The Late A-Group pottery is strongly characterized by thin eggshell wares with geometric-painted decoration, ripple wares, red polished wares, black-topped bowls, coarse wares with Rocker stamp dotted zigzag decoration, and open bowls with complex incised decoration (Nordström 1972).

From Foraging to Food Production: The Early Neolithic of the Central Sudan (Fig. 5)

The first Neolithic settlement excavated in the central Sudan (Shaheinab: Arkell 1953) has been until recently considered the type site of the Early Neolithic of the region. After Arkell's excavation, archaeological research was focused on cemetery sites (Kadero, Ghaba, Kadada, Es Sour, Al Khiday 4). The few Neolithic settlements tested (Geili, Kadero middens, Sheikh el Amin, Haj Yusif) turned out to be heavily destroyed by later human and natural post-depositional disturbances.

The recent publication of the Ghaba (Salvatori et al. 2016) and Kadero (Chłodnicki et al. 2011) cemeteries allows the development of a new and more complex picture of the Early Neolithic of the central Sudan. The Ghaba cemetery, where 265 Neolithic graves were excavated in one fourth of the estimated archaeological area, revealed the presence of a Neolithic phase older than the Shaheinab one. Seriation of the Ghaba cemetery and radiometric determinations allow the dating of the first phase that we call the Ghaba phase (5300 and 4650 BC), followed by Shaheinab phase A (4650 to 4300 BC) and Shaheinab phase B (4300 to 4000 BC).

At present the Ghaba period seems to be present only in the Shendi area (northern central Sudan), while the later Shaheinab phases spread all over central Sudan from Shaqadud in the Butana to the south along the Blue and the White Nile. These different periods are characterized by distinctive pottery assemblages. The main pottery types of the oldest period are red-slipped black-rimmed biconical jars, hemispherical restricted undecorated boat-shaped bowls, sub-cylindrical decorated beakers, undecorated

Ceramic Production in the Middle Nile Valley, Sudan (8000 BC–1500 AD), Fig. 5 Selection of diagnostic pottery shapes and decorations from central Sudan. Early Neolithic A and B (redrawn from Salvatori et al. 2016); Late Neolithic (redrawn from Reinold 2007)

bowls, bowls decorated with rocker stamp dotted and plain zigzag motifs, wolf-tooth patterns and with impressed semicircles realized with a double-pronged tool, and caliciform beakers, among others (Fig. 5 Phase A). Some of the pottery types and decorations are known in the contemporary Middle Neolithic A of Upper Nubia, suggesting a colonization of the Shendi area by people coming from the north from the last centuries of the sixth millennium BC (Salvatori et al. 2016). The Neolithic pottery of the central Sudan is still made by coiling and thinned using a paddle and anvil technique.

The later Shaheinab period pottery is characterized, in the Ghaba and Kadero cemeteries as well as at Shaqadud, Shaheinab, Geili, Gereif East, Haj Yusif, and Sheikh al Amin settlements among others, by red-coated, very well-polished to burnished bowls, red-burnished biconical jars, unrestricted and restricted globular and hemispherical bowls with rocker stamp unevenly spaced dots (more often occurring in settlement deposits than among grave goods), mainly well-polished to burnished red globular bowls decorated with hanging dotted concentric semicircles arranged in four symmetrical panels, and black-rimmed red-burnished bowls (Fig. 5, Phase B). Shaheinab period represents, like the Middle Neolithic B phase in the north, a consolidation and expansionist period of the communities of the central Sudan. The end of the Shaheinab period presents few but interesting differences with the appearance of bowls decorated with concentric incised semicircular lines hanging from the rim which abruptly replace the similarly arranged dotted decoration type.

The Late Neolithic of the Central Sudan (Fig. 5)

At the beginning of the fourth millennium BC, the Shaheinab final phase disappeared being replaced almost everywhere by new types of pottery and lithic production. Vessel shapes are mainly ovoid and globular jars (e.g., Reinold 2007: Figs. 211–273) and various types of black burnished bowls from open to restricted forms. Decoration is stippled impressed or incised, sometimes producing very complex designs (e.g., Reinold 2007: Figs. 180–210; Caneva 1988: Fig. 10), and is mostly rippled. The typical Shaheinab gouges (rhyolite stone tools possibly used in wood working) are now replaced by polished axes.

This Late Neolithic phase can be dated on the base of radiometric determinations from Kadada to about 4000 to 3300 BC. Its distribution is known from the Shendi area to Khartoum and possibly to the south as is suggested by the graves excavated at Goz Kabbaro in the Gezira, along the western side of the Blue Nile (Balfour Paul 1952).

In the western desert and mainly in the western part of the lower Wadi Howar, Neolithic settlements and camp sites, C14-dated to the fourth and early third millennium BC, have been located by the University of Cologne (Jesse 2010: Fig. 6). Pottery from several sites, and mainly from the Abu Tabari area, is characterized by a decorative style named Leiterband that is well known also in the middle Wadi Howar. Another distinctive decoration associated with the Leiterband motif is the herringbone-incised pattern (Jesse 2010: Figs. 9 and 11) which has been compared to Late Pre-Kerma samples dating to the beginning of the third millennium BC. From a different perspective, the Leiterband decoration and more specifically its oldest phase at Djabarona 84/13 have been compared with the Rocker stamp unevenly spaced dot decoration typical of the Shaheinab phase of the Early Neolithic of the central Sudan. This very strong similarity suggests a date for this decoration type in the second half of the fourth millennium BC.

The Protohistoric Context in Nubia (ca. 2400–1500 BC)

The third millennium BC is mainly known from Nubian contexts, the central area of Sudan being archaeologically silent for this period. Two distinct groups of peoples, namely, the C-Group in Lower Nubia and Kerma in Upper Nubia, follow on from the ceramic tradition of the previous A-Group and Pre-Kerma inhabitants of the Middle Nile valley.

The C-Group of Lower Nubia (2400–1500 BC)

The C-Group people is considered to be related to the A-Group in Lower Nubia. The latter withdrew

to the oases of the western desert for four centuries before again coming close to the Nile, probably pushed back by the final drying up of the Sahara. The connection between both ceramic industries is obvious: black-topped and incised or impressed ceramics continued to be the most identifiable production of the C-Group potters (Williams 1983: 25–63). Some differences or developments can nevertheless be noticed: C-Group potters favored the use of a dung temper probably taken from their cattle, while A-Group ceramics used various materials including ash temper. Shapes, still handmade, became more rounded even if there is no radical change within the typology.

The C-Group culture has been divided in four phases established from documentation mainly collected in cemeteries such as Aniba, Qurta, Dakka, Faras, Adindan, and Serra. Criteria such as the variety of burial customs, the Egyptian imports, and the evolution of incised decorative patterns on ceramics were taken into account (Hafsaas 2005). Indeed, the study of the structure of the incised designs shows various combinations evolving throughout the end of the third millennium and the first half of the second millennium BC. During the first phase (phase1/a, ca. 2400–2160 BC), the plaited pattern, the half-moon pattern, and the quadrates pattern were incised on black bowls (Fig. 6a–c). Wavy lines incised on the rim appear to be restricted to this period. The quadrilateral structure of the patterns is diagnostic of the second phase (phase 1/b, ca. 2160–1985 BC). The division of the decoration allows various combinations of simple geometric forms such as rectangles, lozenges, and triangles that have been named the quadrilateral plaited pattern, the quadrilateral quadrates pattern, and the chevron pattern (Fig. 6d–f). The third phase (phase 2/a, ca. 1985–1650 BC) is marked by the first appearance of figurative-incised decoration. Other motives such as zigzag patterns, herringbone patterns, and chessboard patterns seem to be characteristic of this phase (Fig. 6g–h). The last sequence (phase 2/b,

Ceramic Production in the Middle Nile Valley, Sudan (8000 BC–1500 AD), Fig. 6 C-Group main designs incised on ceramics (Redrawn from Hafsaas 2005)

ca. 1650–1500 BC) is characterized by a diamond structure in the incised designs on pottery (Fig. 6i). The filling of the incisions with red and yellow pigment appears to be confined to this phase. We lose track of the C-Group people when their Egyptian neighbors conquered Nubia. They are thought to have blended into the new Egypto-Kushite society which emerged from that colonization.

Kerma Pottery in Upper Nubia (2450–1450 BC)

Named Kush in the Egyptian sources, the kingdom of Kerma settled the area south of the Second Cataract as far as south of the Fifth Cataract at the culmination of its power. Descendents of the Pre-Kerma people and probably also related to the C-Group, the Kerma potters produced a pottery that one can think of as one of the most remarkable accomplishments of Nubian culture.

The excavations conducted at Kerma and Sai have considerably improved our knowledge of Kerma culture and allowed scholars to define four phases (ancient, middle, classic, and recent) on the basis of ceramic evolution (Gratien 1978). Ancient Kerma (ca. 2450–2050 BC) is probably connected to the A-Group and corresponds in various ways to the C-Group early assemblages. As for the C-Group ceramics, Nile silt and dung temper are the basic recipes of all the pots produced. Black-topped and red- or black-incised bowls are fairly common. The typology consists of bowls with a pointed base and decorated with an incised line on the rim. During Middle Kerma (ca. 2050–1750 BC), ceramic production tends to separate gradually from that of the C-Group. Black-topped bowls are more finely executed, but the previous red- or black-incised bowls, sometimes associated with large crude bowls decorated with incised triangles below the rim and wide jars with a restricted neck and flaring rim, are still attested. Classic Kerma (ca. 1750–1550 BC) is known for the famous "tulip beakers" (Fig. 7, right) which mark the final evolution of the black-topped pottery tradition. The thickness of the wall of the ceramics that does not exceed 3 mm, as well as the quality of the finish with the surface brightened to a metallic sheen, is evidence of the high level of craftsmanship of the Kerma potters. This peculiar production was well diffused within Kerma territory and also in Egypt: a few of these beakers have been found as far away as the Egyptian Delta. The potters were also able to create new fashions of painted wares and plastic decoration. The disparity between Kerma and C-Group ceramic industries is in this phase obvious, notably from a technical point of view: even if the typology is quite similar, the pots are better fired, better finished, and thus correspond to a finer version of C-Group pottery. Nevertheless, the incised designs that are so frequent in C-Group pottery are less common in the Kerma ceramics. The complexity of the patterns executed and described above has no parallels further south. The final phase of Kerma (ca. 1550–1450 BC) is hardly known. It corresponds to the period after the Egyptian conquest of Nubia, and the local ceramics appear to be marked by the influence of Egyptian pottery production.

Ceramic Production in the Middle Nile Valley, Sudan (8000 BC–1500 AD), Fig. 7 Kerma Pottery (© J.-F. Gout)

The Egyptian Conquest and Its Influence on Nubian Pottery (ca. 1550–270 BC)

The Egyptian conquest of Nubia and the long-term settlement of Egyptians (administrative, military, etc.) in new-built towns and fortresses deeply marked the indigenous Nubian pottery craft. The first evidence of such influence is the introduction of the potters' wheel to fashion the ceramics.

Nubia Under the Egyptian Power (ca. 1550–1000 BC)

As an introduction, we have to warn the reader that our knowledge of this period almost exclusively results from the excavations of Egyptian towns, temples, and fortresses built in Nubia. The consequence for the broad picture of ceramic industries of this phase is that we miss data from indigenous contexts which likely coexisted with the Egyptian conquerors. As a matter of fact, the handmade ceramic tradition inherited from C-Group and Kerma populations survived during this period. Nubian cooking pots were still produced, and Nubian potters, despite the introduction of the wheel, continued to follow the Egyptian fashion with their own know-how.

Many of the ceramics from all the sites (see Holthoer 1977) dating to the Egyptian domination of Nubia show a great similarity to Egyptian vessel types. To this extent, Egyptian chronology is followed to assign a date to productions, and the Egyptian ceramic classification system, the "Vienna System," is commonly adopted to describe wares that were obviously made in Nubia (Arnold and Bourriau 1993). Wheel-made dishes, deep carinated bowls, beer jars, and large storage jars or *zîrs* as well as handmade bread plates are common and remarkably similar to their Egyptian counterparts. Most of them are made in Nile clay, a raw material of course available both in Nubia and in Egypt. Petrographic analyses have been undertaken to distinguish genuine Egyptian Nile silt imports from their Nubian imitations. The clay matrix being the same, only few details like grain-size, proportion of non-plastic inclusions and organic remains suggest a technical variability that might be significant (D'Ercole et al. 2017). Other features such as surface treatment (burnishing) or decoration (incision) can help to define a local style even if the shape is of an Egyptian type. A small proportion of ceramics made with marl clay, which is only found in Egypt, is likely evidence of imports. They illustrate the role of the Egyptian state in providing commodities to its southern colonies.

The other mode of production to consider is the indigenous Nubian. In the earliest levels of Egyptian sites built in Nubia, cooking pots and Classic Kerma beakers are still attested but were soon replaced by ceramics better adapted to Egyptian taste. This does not mean that the Nubian handmade pottery tradition disappeared totally, as it is revitalized during the subsequent Napatan and Meroitic periods, but the Nubian craftsmen had to adapt their skills to fashion Egyptian types of ceramics. They were probably trained by Egyptian potters in the use of the wheel, and then they passed down this new technology to the next generations.

The Napatan Period and Its Pottery Production (ca. 1000–270 BC) (Fig. 8)

The withdrawal of the Egyptians from Lower Nubia toward the beginning of the first millennium BC is contemporary of the emergence of a new Nubian elite who chose Napata, close to the Fourth Cataract, as a capital city. The first phase of the sequence is insufficiently known, since only few contexts dated from tenth to eighth centuries BC have been discovered (e.g., Vincentelli 2006). The influence of Egyptian production appears to remain important, with a large number of wheel-made bowls with red-painted rims, imported "pilgrim flasks," and amphorae. Some handmade Nubian products, notably red-burnished bowls, black-topped goblets, and globular jars, testify to the continuity of the traditional Nubian pottery craft. We can however notice that incised and impressed designs are very simple, with some rare lines and very simple geometrical forms.

The eighth century BC is marked by the Nubian conquest of Egypt, and the noticeable influence of Theban pottery on the typology of Nubian wares. In addition to a large quantity of imports from Egypt, the local repertoire shows attempts to follow Egyptian models. In the earliest Napatan levels of Kerma (Mohamed Ahmed 1992) dated to the second half of the eighth century BC, some handmade local productions correspond to Egyptian shapes. This trend goes on during the following century with local wheel-made jars with rounded to more sophisticated rims, ribbed bodies, and ovoid shape, sometimes painted in white that correspond to

Ceramic Production in the Middle Nile Valley, Sudan (8000 BC–1500 AD), Fig. 8 Examples of Napatan pottery, WT 1 Cs 09 and II T 105 Cd 01 (© Sedeinga mission, Juliette Laroye, Vincent Francigny)

the natural color and form of the imitated marl production.

From the second half of the sixth century and during the fifth century BC, Egyptian influence on Nubian pottery seems to become less important. The study of a potter's workshop dated to this period (Mohamed Ahmed 1992) illustrates this evolution. The wheel is still widely used to shape ceramics, but the typology evolves differently from that of contemporary Egypt. The jars are less elaborated, rims are simple, and bodies move from ovoid to more globular in shape. Handmade vertically red-burnished bowls of different sizes characterize this period in Nubia. The imprint of Egypt is nonetheless visible in cultic contexts where bread cones and other platters of an Egyptian origin were still produced.

The end of the Napatan period is not well known except from rare royal or elite funerary contexts at Nuri and Meroe. These demonstrate a certain taste for luxurious imported commodities (Dunham 1957). In parallel, the daily local production consists mainly of the handmade red-burnished deep bowls previously described, and a variety of wheel-made or handmade simple jars carelessly executed. The transition to the Meroitic period is far from understood. No contexts dated from the fourth to the beginning of the third century BC allow a description of the evolution of the ceramic industries.

Nubian Pottery and the Mediterranean World (ca. 270 BC–1500 AD)

The Meroitic Productions (ca. 270 BC–340 AD)

The earliest levels of the Meroitic period contain black handmade ceramics that are completely different from their late Napatan counterparts (Fig. 9a). The various types of ceramics, characterized by their black color and impressed decoration, fit clearly within the sub-Saharan tradition and represent a clear continuity from some Kerma and C-Group ceramics that had been absent from Nubia for more than a 1000 years (Adams 1986, 411–420). On the other hand, the omnipresence of handmade production reveals the cessation of use of the potter's wheel in Sudan between the late Napatan and the early Meroitic periods. Such disruptions in the ceramic tradition likely demonstrate a migration into Nubia of a population that preserved the sub-Saharan ceramic tradition.

The handmade ceramics are associated with wheel-shaped pots from the second century BC, but as mentioned above, the typology does not show continuity from the Napatan period but are adapted from the local handmade repertoire or are

Ceramic Production in the Middle Nile Valley, Sudan (8000 BC–1500 AD), Fig. 9 Examples of Meroitic pottery. (**a**) handmade jar from Sedeinga, I T 027 Cs 06 (© Sedeinga mission, Romain David); (**b**) painted crater from Muweis, Mws11-A-F11.Cer1 (©Musée du Louvre-Mission archéologique de Mouweis-Marie Evina); (**c**) stamped bowl from Sedeinga, I T 087 Cc 01 (© Sedeinga mission, Romain David); (**d**) painted bowl from Berber, B-1-6 (©Berber mission, Romain David)

directly inspired by Hellenistic forms such as craters (Fig. 9b) and tablewares. The adoption of these new forms and techniques was followed by the introduction of painted decoration following Hellenistic models, such as wavy lines, vine scrolls, and other floral motives that demonstrate the growth of influence of Ptolemaic Egypt on Meroitic ceramic production until the change of the era.

The first decades of the first c. AD are marked by the introduction of *fine ware* ceramics (Adams 1986, 435–439). For the first time, this type of production made use of kaolinitic clay. Potters used all the potential of the wheel to shape new forms borrowed from Roman ceramics, bronze, and glass vessels, and Hellenistic techniques were employed for stamped decoration (Fig. 9c). The *fine ware* production appears as the result of a transfer of knowledge from the Roman Empire to the Meroitic kingdom: potters integrated several techniques and shapes into their own repertoire while immediately adapting the stamped decoration method to their own iconography. The light-colored surface of the vessels became a major medium to develop religious themes, influenced by Pharaonic, Ptolemaic, and Romano-Egyptian iconography as well as local features (Fig. 9d). The beginning of our era witnessed the important development of the wheel-made ceramic industry. Its significance is particularly noticeable in funerary contexts, particularly in Nubia and in the Meroe region, where they totally supplanted handmade vessels by the end the first c. AD.

After two flourishing centuries, the unity of the Meroitic kingdom weakened during the third c., to finally fall apart by the fourth c. AD when it was replaced by smaller political entities. The ceramic industries, like other economic activities, were heavily impacted by this change. The first evidence is the impoverishment of the ceramic repertoire, both its typology and its iconography. First, the *fine ware* industry was gradually replaced by cheaper imitations, fashioned with alluvial or mixed clay and poorly decorated. In the Meroe region, the genuine *fine wares* disappeared during the third c. AD, replaced by their semi-fine counterparts. Simultaneously, the decoration of Meroitic ceramics, both painted and stamped, became gradually simpler and completely disappeared during the course of the third c. AD. The decline that characterizes the painted decoration on Meroitic ceramics during the third c. AD is most probably related to the

disappearance of some *fine ware* workshops, which hosted both the painting skills and the iconographic knowledge.

Regionalization of ceramic production, a process initiated few centuries before, seems to be finalized during the third c. AD. In Nubia, the regional repertoire of shapes lost the common traits it previously shared with the southern regions. In the south, new shapes such as cylindrical jars that were widely distributed at Meroe during this period are specific to the region and are not represented in Nubia. These features presage the dichotomy highlighted during the post-Meroitic period.

The historical decline of the Meroitic kingdom appears rather clearly in ceramic production, which industry evolved radically during the fourth c. AD. Often imprecise, the archaeological documentation shows nonetheless that a short ceramic transition took place at the very end of the Meroitic period, announcing the general patterns of the post-Meroitic assemblage.

The Post-Meroitic Dichotomy of the Sudanese Industry (ca. 340–550 AD) (Fig. 10)

As early as the third century AD, some discreet evidence demonstrates the gradual withdrawal of a cultural group coming from the south to the region of Meroe. It is distinguishable by some handmade black bottles and the so-called *Alwa wares* mainly found in funerary contexts (Lenoble 1992). This group is likely the one who gave the final deathblow to Meroitic power weakened by the war against the kingdom of Axum. At the beginning of the fourth century AD, the assemblages in the former southern area of the Meroitic kingdom show on the one hand continuity with the practices and the typology inherited from the third century AD, with elongated wheel-made jars and ledge-rimmed bowls made in Nile silt, and, on the other hand, the appearance of new handmade standardized jars with surface treatment consisting of mat impressions. The type is so distinctive of the period in the regions south of Nubia that it has become the chronological as well as the cultural marker of the post-Meroitic period (Lenoble 1992). The diversity encountered in size, in shape, and in surface treatment probably evidences chronological evolution as well as various centers first settled in the Shendi area and later in the Fourth Cataract region (El-Tayeb 2012).

Ceramic Production in the Middle Nile Valley, Sudan (8000 BC–1500 AD), Fig. 10 Examples of post-Meroitic pottery from Dangeil (©Dangeil mission, British Museum, Romain David)

Indeed, the material from the Fourth Cataract region and up to the Third Cataract shows the same profile as observed in the region of Meroe, with the same more limited range of forms and decoration than during the Meroitic period. What was originally named the "Tanqasi culture" shares common features with the heartlands of the former Meroitic kingdom (El-Tayeb 2012). The handmade jars with mat-impressed surfaces are also frequent in funerary contexts where they are associated with red-slipped wheel-made goblets. A new type of wheel-made bowl with incised lines below the rim appears during the fourth century AD and enters into the usual funerary material of this region where it forms a long-term component of the funerary assemblage.

This particular design is probably due to the influence of Nubian post-Meroitic production that

evolved differently. From the Third to the First Cataract, a complete shift of ceramic production is obvious: clay coming either from the Nile or from the desert is more finely levigated, typology is more influenced by contemporaneous Egyptian prototypes than inherited from the Meroitic shapes, and occasional painting of vertical stripes and festoons following Egyptian trends applied on a red ground is the main decorative scheme (Adams 1986, 458). The extreme standardization of wheel-made production in Lower and Middle Nubia suggests a limited numbers of workshops supplying the region. The kilns located at Debeira East (Adams 1986, 34–36) are large-scale enough to ensure mass production able to supply a wide area. Concerning the local handmade production, besides the continuity of some cooking wares, new forms of red-slipped vessels associated with new painted decoration illustrate the development of this industry.

The main features of the ceramic productions established during the post-Meroitic period – the dichotomy of the former Meroitic kingdom with a gradual rise of the handmade tradition in the south, while the north promotes wheel-made mass production – lay the foundations for the situation of the subsequent medieval period.

Medieval Pottery (ca. 550–1500 AD)

The political division of the Meroitic kingdom illustrated by the ceramics was formalized during the sixth century AD. Three, soon to become two, Christian kingdoms, Nobatia and Makuria in the north and Alodia or *Alwa* in the south, whose border was likely located in the area of the Fifth Cataract, represent the achievement of a cultural process initiated during the Meroitic period.

Thanks to the UNESCO salvage campaign in the early 1960s and to the work of W.Y. Adams in Lower Nubia, the chronological evolution of the pottery production in the Makurian territory is quite well defined (Adams 1986, 47–55). Medieval or "Christian" pottery has been divided into five phases (Early, Classic, post-Classic, Late, and Terminal) by means of the evolution of the ceramic features.

The Early Christian phase (ca. 550–850 AD) is characterized by a slow transition from post-Meroitic types. No particular trends seemed to occur in handmade production, and the wheel-made wares were gradually shaped according to Egyptian Late Roman sigillata models produced at Aswan. As a consequence, the clay mixture was as fine as possible to produce open shapes that were then covered with a highly polished red or orange or white slip. Painted decoration was limited to few painted bands, while stamped designs of religious motives were frequent. Debeira East and Faras are known to provide such Nubian sigillata wares that were distributed as far as the Fourth Cataract region.

The Classic Christian phase (ca. 850–1100 AD) is marked by the noticeable evolution of wheel-made production that shows a revival of the painting tradition on red-, white-, and yellow-slipped ceramics, the typology of which continues to be linked to the styles observed at Aswan. The motives were likely inspired by religious themes previously used in manuscripts and church frescoes. The factory of Faras was at the peak of its production in Lower Nubia, while Old Dongola and Ghazali workshops were still in development in Upper Nubia. At the end of this phase (ca. 1000 AD), Faras was abandoned as a major production center, while the two other sites were reaching their apogee. Generally speaking, the decrease of local products caused by the collapse of the factory of Faras was offset by a considerable rise of Aswan imports in Lower Nubia.

A short post-Classic phase (ca. 1100–1150 AD) clearly shows continuity with previous productions. The absence of evidences of major factories in Lower Nubia during this period while we know that the workshops of Old Dongola and Ghazali were still in use might explain the slight evolution demonstrated by the increase of the red-slipped wares and the introduction of orange-slipped vessels clearly distinct from yellow- or white-slipped Classic ceramics.

The Late Christian phase (ca. 1150–1350 AD) shows a progressive standardization of wheel-made production that might represent a shift from few to only one manufacturing center furnishing the whole Nubian region. A slow

transition in terms of decoration toward more simple linear designs used on a freshened set of forms is the main feature of this period.

In contrast to the previous period, the rare ceramic material dated to the Terminal Christian phase (1350–1500 AD) seems to demonstrate a significant increase of workshops illustrated by the introduction of new wheel-made wares. Fine table wares or utility vessels were produced in low quantities in new local centers that disappeared at the very end of the period and were totally supplanted by a range of handmade productions.

By comparison, the development of ceramic production in the kingdom of Alodia is far from understood (see Welsby 1998). As observed in the post-Meroitic period, handmade burnished black and red pottery continues to form the main ceramic corpus available in the south. The evolution of the typology remains unknown and difficult to trace as the types tend to maintain the same characteristics over a long time span. A distinctive wheel-made production called "Soba ware," named after the capital of the kingdom of Alodia, seems to be confined to the early medieval period and is limited to a few types of open shape including some borrowed from northern sigillata. However, their painted polychrome decoration over a dark slip is distinctive.

Conclusion

The study of long-lasting pottery traditions in the middle Nile valley provides the main tool with which to establish the chronological sequence of the archaeology of the Sudan. From the Mesolithic to Medieval times, the evolution of ceramic production has highlighted major changes in cultural and, to a lesser extent, political terms. However, only the visible modifications such as typology, decoration, and the way of shaping the pots can be taken into account. Research concerning the subtle changes of the *chaîne opératoire* that might be significant in considering the complexity of the potter's network, to distinguish various workshops and technological know-how in the same region, are still ongoing. Petrographic and chemical analyses are thus playing a major role in defining persistent features in clay preparation (D'Ercole et al. 2017). Other aspects, particularly the precise definition of fashioning methods, are currently underexploited in Nubian studies but can be expected to reveal essential information about the transmission of skills among potters. Archaeological investigations of more production centers will also bring useful data. Up to now, only a few pottery workshops (Faras, Argin, Debeira, Ghazali, Musawwarat es-Sufra) of a late date have been studied.

Finally, another promising field is research conducted on the margins of the Nile valley, in the western and eastern desert and in the south (e.g., Barnard 2008). The role of nomads in preserving and influencing pottery practices of the Nile valley has not yet received the attention it deserves. Many current archaeological issues would find here a useful source for consideration.

Ceramics as Dating Tool in Historical Archaeology

Charles E. Orser Jr.
Department of Anthropology, New York State Museum, Albany, NY, USA

Brief Definition of the Topic

Historical archaeologists have learned that excavated ceramics can be used to date the sites they study. The most useful ceramics for dating are the glazed, relatively highly fired, fine -bodied earthenwares common since the late eighteenth century.

By around 1750, European ceramic manufacturers had begun a concerted effort to mass-produce fine-bodied, durable earthenwares for the world market. Their overall plan imitated the Chinese, who had already developed porcelain factories for the production of vessels explicitly designed for export. The Europeans also attempted to mimic the porcelain itself by initially producing white-bodied earthenwares with blue decorations similar to those found on the Asian wares. European potters viewed their glaze formulas, decorative motifs, and production techniques as company-owned trade secrets, and because they worked within a competitive commercial environment, they usually kept meticulous records of their patterns, styles, and methods of manufacture. Historical archaeologists can use extant potters' records to date the creation and production of certain ceramic styles. Even where written records do not exist, historical archaeologists can use ceramic collections from several archaeological sites to chart the general trends of adoption, use, and eventual rejection of ceramic styles and patterns over time.

By the mid-nineteenth century, many potters had begun to put their company names – as well as symbols and even pattern names – on the bottoms of their pieces as marks of identification. Historical archaeologists can use these makers' (or bottom) marks – embossed, stamped, inscribed, or applied – to date specific pieces by referring to the ceramic historians' published catalogues of marks.

The use of makers' marks are relative dating tools because they provide a range of dates or perhaps only a beginning date for a certain style of ceramic. For example, a potter working in Staffordshire, England – the nineteenth-century's most prolific region – might be known to have used the mark of a crown set over the letters "EM" starting in 1813. The available records may not indicate precisely when the potter ceased using this mark. Upon finding a ceramic shard with this mark, however, an archaeologist would know that the specimen dates after 1813; he or she might even be able to date its end use by reference to other information.

In the 1970s, an archaeologist named Stanley South invented a more absolute way of dating collections of mass-produced, English ceramics. Using ceramic information mostly collected by another archaeologist, Ivor Noël Hume, South created a statistical formula that archaeologists could use to provide the mean date for an entire ceramic collection. Using his calculation, a ceramic collection from an archaeological site might yield a mean ceramic date (or MDC) of 1835. With this date in hand, archaeologists can apply another statistical tool, called the standard deviation (SD), to improve the reliability of this date. A collection with a mean date of 1835 might be found to have a standard deviation of 10. This would mean, with a greater degree of certainty that the mean ceramic date actually falls within the 1825–1845 era (± 1 SD). Mean Ceramic Dating, though not without problem, still finds application in historical archaeology. In some cases, however, archaeologists using the formula must account for time lags in shipping and marketing.

Ceramics, Ancient Greek

Antonis Kotsonas
Amsterdam Archaeological Centre – Allard Pierson Museum, University of Amsterdam, Amsterdam, The Netherlands

Introduction

For scholars and the general public alike, ancient Greek ceramics are iconic images of ancient Greek culture and occupy a prominent place in the history of Western art. Because of their indestructibility, variety, and wide distribution, ancient Greek ceramics form a major field of research for Classical and Mediterranean archaeologies. It is mostly the exceptionally complex figural scenes rendered on these artifacts that have fascinated modern audiences and attracted research by specialists. Figured but also plain pottery provides information about ancient Greek society, daily life, economy, and ideology. Furthermore, Greek pottery, like all archaeological ceramics, helps to identify and date sites and deposits, distinguish between activities in different places and document contact between people, Greeks and non-Greeks.

Definition

The term "ancient Greek ceramics" can be taken to refer to vessels produced from baked clay in all lands of the Mediterranean and the Black Sea inhabited by Greeks during a period which ranges from the eleventh century BCE, which stands for the conventional end of prehistory, to the first century BCE, by which time the Romans conquered the entire Greek world. Not all scholars have perceived the term in a similar fashion (Oakley 2009: 599). Up to the mid-eighteenth century CE, this pottery was not even considered Greek, but Italian, and was attributed to the Etruscans because of major discoveries made in Etruria. Recently, some scholars consider that Greek pottery covers the varied output of potters/painters not only of Classical but also of Prehistoric Greece. Conversely, others limit the use of the term to the pottery produced in the central and southern Aegean from the eighth to the fourth century BCE, often focusing on Attic pottery from the sixth and fifth centuries BCE.

Historical Background

Ceramic production was introduced in Greece from the Near East in the seventh millennium BCE, during the Neolithic period, and intensified in the course of the Bronze Age, not least because of the introduction of the fast-rotating wheel (traditionally dated c. 2000 BCE). Wheel throwing was the most widespread technique for much of the first millennium BCE, but other techniques (such as coiling) are also amply documented, especially for coarse and cooking wares. Ancient

ceramics are nearly as durable and versatile as modern day plastic. Clay was not the only raw material which was used for the manufacture of containers in Greek antiquity, but the one which was most widely used and survives best. Vessels made in other materials survive only rarely, though their impact is sometimes reflected on the pottery itself (skeuomorphism): basketry and wickerwork influenced the styles of early Greek pottery, while an influential debate has focused on whether Attic Late Archaic and later pottery copies expensive metal vessels, particularly silverware (Sparkes 1996: 145–51).

Ceramic production (on the modes of which, see Cook 1997: 259–62; Boardman 2001: 139–52; Mannack 2002: 23–32; Stissi 2002: 10–179) involves the basic elements of earth (clay), water, and fire. Ancient Greek potters worked in isolated facilities or in potter's quarters, which were within or – mostly – outside the settlement, preferably along major communication routes facilitating transactions. Outside the cities, pottery making was probably run in families and was a seasonal, part-time profession. For Athens, Corinth, and other centers of the Archaic and Classical periods, we assume a more intensive mode of production, involving personnel of several hundreds at any one time. Inscriptions rendered on vases indicate that some of the potters/painters in Athens had some degree of literacy and suggest that some were slaves or immigrants (Boardman 2001: 143–9; Wachter 2001; Stissi 2002: 111–21). Marks on mid-sixth to mid-fifth century BCE Attic vases further entail a communication code between potters/painters and traders and demonstrate that the origins of the traders were not necessarily similar to the provenance of the pots, that is, Attic pottery was occasionally exported by foreign traders (Boardman 2001: 153–67; Johnston 2006: 16, 28). The marks sometimes indicate prices, which are low, but rise in the case of long-distance transport (Sparkes 1996: 140–5; Stissi 2002: 189–210; Johnston 2006: 19–23).

Pottery was essential for a wide range of daily activities in ancient Greece (on use see Sparkes 1996: 64–89; Cook 1997: 207–29; Boardman 2001: 244–68; Stissi 2002: 211–87). A broad repertory of shapes accommodated the varying needs of storing and transport, cooking and food processing, and eating and drinking. People used pottery in public games, festivals, symposia (drinking parties) and religious rituals or dedicated it to sanctuaries. Ceramics were also essential in funerals, in containing oils for anointing the dead and wine for libations, providing for the funerary meals or serving as gifts. Vases were customarily buried with the dead and large pieces (pithoi and amphorae) were also used as coffins and urns or even as grave markers. Pottery carrying offerings was also used and/or placed at the graveside on later occasions, as an act of remembrance. In certain times and places, particular shapes/types and decorative scenes were considered appropriate for particular occasions or social groups. Women are usually associated with vessels like pyxides, lekanides, and alabastra, men with kraters and aryballoi. Such gender differentiations are also often reflected on the iconography of the pottery (Sparkes 1996: 68–89; Smith and Plantzos 2012: 17–25).

The stylistic development of ancient Greek ceramics is quite complex, much more than the following overview suggests: (Cf: Sparkes 1996: 3–27; Cook 1997: 5–205; Boardman 2001: 11–127; Mannack 2002: 65–167; and Smith and Plantzos 2012: 39–104. For Protogeometric to Archaic, see Boardman 1998 and Coldstream 2008. For Late Archaic and Classical, see Sparkes and Talcott 1970. For Hellenistic, see Rotroff 2006). The collapse of the palatial sociopolitical system of the Greek Bronze Age (c. 1200 BCE) brought about a demise in the production and circulation of Greek pottery. The eleventh century BCE is characterized by a ceramic repertory with a reduced number of shapes featuring simple decorative ornaments and an increase in the production of handmade (as opposed to wheel thrown) pottery. The ceramic style which emerged is a debased version of earlier styles and is therefore known as sub-Mycenaean (sub-Minoan in Crete). There is a sharp contrast between the varied, curvilinear ornaments on Greek pottery of the late second millennium BCE, which are drawn freehand, and the relatively limited repertory of stylized ornaments (particularly circles and semicircles) normally drawn by multiple brush, which are introduced just before 1000 BCE. The

impression of geometry conveyed by the shape and decoration of Greek pottery of the early first millennium is reflected in the stylistic terms Protogeometric and Geometric, applied to fine wares of the late eleventh to tenth and the nineteenth to eighth centuries, respectively. The Protogeometric style (Fig. 1: the vase represents the persistence of this style in later times, during which it is known as sub-Protogeometric) involves the application of a gloss of lustrous quality (which first appeared in Athens and slowly spread to other areas) over a large part of the vessel's surface and a narrow range of ornaments in reserved areas. The Geometric style (Fig. 2) is characterized by several new shapes and a much wider range of largely rectilinear ornaments, most notably the meander. From the second quarter of the eighth century BCE, figural decoration, which was extremely rare on Greek pottery after Prehistory, reappears. Funerals, battles, and other themes are rendered on the pots with figures in silhouette. For the first time, Greek ceramics carry alphabetic inscriptions, including potter's/painter's signatures (Cook 1997: 241–48; Wachter 2001; Denoyelle and Iozzo 2009: 37–8). From this period, Greek vessels, including the newly introduced transport amphorae (Whitbread 1995), were exported and occasionally imitated in quantity over much of the Mediterranean (Denoyelle and Iozzo 2009: 33–65; Coldstream 2008: 302–27), formulating a pattern which persisted for the rest of antiquity.

Ceramics of the seventh century BCE are often called Orientalizing because of the Near Eastern influences seen on their iconography of flora, fauna, and humans (Fig. 3). Orientalizing influences are, however, only seen on a fraction of the overall ceramic output, with simpler styles predominating. Silhouette drawing gives way to outline drawing, polychromy, and the black-figure technique, which involves incision and accessory colors (purple red and white) (Fig. 4). These technical developments suited the drawing of complex scenes from Greek mythology. The black-figure technique, which was developed in Corinth in the early seventh century, spread over much of the Greek world between 620 and 480 BCE. Black-figure enabled more naturalism and finer detail than ever before and was perfected by Attic painters (Fig. 5), whose work was appreciated over much of the Mediterranean, particularly in Etruria. Several Attic (but hardly any other) potters and painters signed their works, on the basis of which we know that sometimes the potter was also the painter (Sophilos, Exekias), or the two could be different individuals (Lydos was a painter, Amasis a potter). Inscriptions and details of

drawing in clothing and the human anatomy help distinguish the hands of individual painters of Attic black-figure and also red-figure. The latter technique (Fig. 6), which is the visual contrast of the former, was invented c. 525–520 BCE, at a time of experimentation in Attic vase painting (another technique introduced at the time and used throughout the fifth century BCE involved polychrome decoration on a white ground: Fig. 7). Red-figure was more demanding for vase painters but offered new possibilities. Previously, figures were necessarily depicted mostly isolated and in profile; the new technique, which involves dark relief lines and drawing in dilute, translucent clays, enabled the rendering of spatial depth and of complex poses. Production in both black- and red-figures persisted until 450 BCE, but thereafter black-figure is hardly seen. The first painters to use the red-figure technique, also known as the "Pioneers," were innovative in many ways and are known to have consciously rivaled each other (Euphronios and Euthymides were two of the best). Red-figure vase painting reached its highest artistic level early in the fifth century BCE and in

Ceramics, Ancient Greek, Fig. 6 Attic red-figure krater, 425–400 BCE (APM 6262). (Courtesy of the Allard Pierson Museum, University of Amsterdam)

this century this craft often echoes monumental art (architecture, sculpture, and painting). From the fourth century, the repertory of Attic vessel shapes made in red-figure shrinks, but the best vases show elaboration with crowded, multilevel scenes, the use of added colors, and the application of relief figures. Attic red-figure pottery, which was widely exported in the Mediterranean, ceased to be produced around 330–320 BCE, but by that time it had stimulated local production in a few regions of the Greek mainland and most notably in South Italy and Sicily (Trendall 1989; Denoyelle and Iozzo 2009: 97–202). Greek pottery was being made there since the time of Greek colonization in the eighth century, but red-figure production became particularly widespread and developed into regional variants, extending from the advanced fifth to the early third century BCE (Fig. 8).

Decorated pottery formed a relatively small fraction of the overall ceramic production in the

Ceramics, Ancient Greek, Fig. 7 Attic white-ground lekythos, 450–425 BCE (APM 627). (Courtesy of the Allard Pierson Museum, University of Amsterdam)

Ceramics, Ancient Greek, Fig. 8 South Italian (Lucanian) nestoris, 425–375 BCE (APM 1842). (Courtesy of the Allard Pierson Museum, University of Amsterdam)

ancient Greek world. Much pottery used in daily life involved less labor input and was only covered in black gloss or remained plain (Sparkes and Talcott 1970; Rotroff 2006). Black gloss pottery was very widespread in the Classical and Hellenistic periods and was often manufactured by workshops which also produced painted wares. Any decoration on this pottery is limited to bands in added colors, ribbing, and incised and stamped patterns or appliqués (Fig. 9). Plain pottery involves a wide repertory of shapes, including some used for cooking and food processing, storage, and transport, which only rarely have any decorated equivalents. Black gloss and plain wares dominate the repertory of Greek ceramics in the Hellenistic period, with a gradual shift to red gloss in the second century BCE. Painted pottery is much rarer than before. West Slope and Gnathia, two popular wares, were produced from the third to the first centuries BCE and involved simple patterns rendered in tan-colored clay and white slip against a black gloss background. Dark-on-light decoration is restricted to a few ceramic centers and is best exemplified by the Hadra hydriae, while polychrome decoration occurs in South Italian pottery, particularly on the third century BCE vases from Centuripe, the figural compositions of which recall the earlier red-figure. Another novelty of the period, which is far more widespread, is the large-scale use of molds, particularly for the production of hemispherical relief bowls with floral and figural decorations (Fig. 10) (Cook 1997: 193–200; Boardman 2001: 122–7; Denoyelle and Iozzo 2009: 203–14).

Ceramic production in Greece obviously outlasted the Roman conquest but thereafter basically conformed to styles current over much of the Roman world. The Romans appreciated Greek art, but apparently did not show any interest in Greek pottery and this lack of interest would persist for more than one millennium and a half (Sparkes 1996: 36–63; Cook 1997: 275–311). Greek vases found their way to the cabinets of curiosities of the Renaissance but were not highly prized by the elites or the artists of the time. From the seventeenth century CE, these vases began to be collected more widely, a trend which became more prominent in the eighteenth century. By the mid- to late eighteenth century, this pottery, previously widely considered to be Etruscan, was correctly identified as Greek on the basis of pre-firing inscriptions rendered on some vases. Slightly later, the first major work on Greek pottery appeared; it is a four-volume, richly illustrated sale catalogue of the sizeable collection of vases amassed by Sir William Hamilton, a British envoy to Italy. Hamilton's purchases, the costly acquisition of his collection by the British Parliament and its subsequent exhibition in the British Museum brought about a serious rise in the appreciation of and demand for Greek vases. From this time onwards, Greek ceramics became a status symbol for the upper class and influenced the work of Western European artists. Scholarship on Greek pottery also flourished and in 1854

Ceramics, Ancient Greek, Fig. 10 Relief bowl (production area unknown), 200–100 BCE (APM 1539). (Courtesy of the Allard Pierson Museum, University of Amsterdam)

Otto Jahn published the vase collection in Munich in what came to be considered the first proper study of Greek pottery (*Beschreibung der Vasensammlung König Ludwigs in der Pinakothek zu München*, München: J. Lindauer).

Key Issues/Current Debates

Provenance and chronology have remained key issues in the study of Greek ceramics and pervade current debates. Other key issues include the development of manufacturing techniques and of styles of decoration, the identification of figural scenes and the attribution of vases to individual potters and painters, as well as the social and economic contexts of pottery production and consumption. These issues are treated in a growing number of publications, including excavation reports, museum catalogues, conference volumes, and other studies. All work is collected and summarized biannually in the "Bulletin Archéologique: Céramique" found in the journal *Revue des Études Grecques*.

The chronology of Greek ceramics (Cook 1997: 249–58; Mannack 2002: 53–61) relies (a) on relative sequences built on the basis of excavation data, particularly stratigraphy, and by the attribution of vases to painters and estimates over the development and overlap of their styles, and (b) on the pegging of these sequences to fixed points, whose calendar dates are known from historical sources. Because fixed points are uncommon in the pre-Classical period, the chronology is less and less accurate as one goes back in time. Major challenges to the traditional chronology were put forward some 20–25 years ago (around 1990). These suggestions have found little support but have raised awareness over some weaknesses in the existing chronology (Oakley 2009: 608–609). Arguments for adjusting parts of the traditional chronology by a couple of decades keep being proposed and are often accepted (i.e., the recently proposed slight down dating of the beginning of red-figure: Oakley 2009: 609), but there is widespread confidence in the precision obtained by the traditional chronology of Greek pottery among archaeologists working in the Mediterranean. Nonetheless, it is essential to check this chronology against scientific dating techniques, like radiocarbon dating and dendrochronology. This issue has not really been taken up, even though the relevant techniques are commonly used by prehistorians working in the Aegean and by specialists of the first millennium BCE elsewhere in the Mediterranean. There are currently two major problems with this line of inquiry; C14 determinations are not precise for much of the first millennium BCE and the dendrochronological data for the Aegean remain very selective. Radiocarbon dates obtained in the Eastern and Central Mediterranean suggest a readjustment of the ceramic sequence of the Greek Early Iron Age, but are not uncontroversial on their own (Smith and Plantzos 2012: 17–25).

Provenance has been a major issue in the study of Greek pottery ever since this was properly identified as Greek. In the last century, research has concentrated on the localization of production of particular vessels, types and wares in specific sites or regions (Oakley 2009: 611), often on the basis of different techniques of chemical analysis. Neutron activation analysis (NAA) has been the technique of choice and has offered invaluable information on the provenance of many Archaic Greek fine wares, most notably those previously grouped under the collective heading "East Greek" (Jones 1986, Fig. 3). Nowadays, NAA gradually gives way to X-ray fluorescence (XRF) spectrometry and inductively coupled plasma emission spectroscopy (ICP-ES), and this makes imperative the comparability of results obtained by different laboratories by the use of different techniques. In recent years, the increasing interest in the circulation of semifine to coarse ceramics brought about the increasing application of petrography, with the first projects appearing in the 1990s (Whitbread 1995). The advantage of petrography lies in its focus on the rocks and minerals found in the fabric (rather than on the clay matrix) of nonfine wares; these inclusions point to a certain geological background which can be traced in the field and thus reveal the specific areas exploited by ancient potters.

Analytical techniques have also been used in research on the manufacturing technology of

Greek pottery (Boardman 2001: 282–93; Oakley 2009: 611–12). Such work commenced in the 1920s and centered on the reproduction of the lustrous Attic black gloss. Thereafter, Attic and, to a lesser extent, other Greek pottery has been the subject of many scientific, experimental, and ethnoarchaeological projects focusing on clays, slips, colors and pigments, forming techniques, drawing tools, firing techniques, and repairs (e.g., Schreiber 1999). Scanning electron microscopy with energy-dispersive X-ray (SEM-EDX) analysis is currently the technique most widely used in technological investigation. This enables a microanalysis of clay and decoration and allows for an estimate of firing temperatures, two subjects which can also be studied by the use of X-ray diffraction (XRD). Likewise, computerized tomography (CT) scans shed light on the method used by the potter for building the pot. The techniques in question have largely overshadowed others previously used in analytical studies of Greek pottery, including optical emission spectroscopy (OES) and Mössbauer spectroscopy.

Applications of archaeological science to Greek pottery of the first millennium BCE remains limited in comparison to applications to earlier pottery from the same area. Even rarer is research on the contents of Greek vases through the study of residue, particularly gas chromatography (GC) and mass spectrometry (MS) or DNA analysis. There are, however, few current projects that employ these techniques, and future work on the production, distribution, and consumption of Greek pottery should increasingly involve integrated, interdisciplinary methodologies, combining traditional approaches with targeted applications of archaeological science.

Issues of provenance and vessel content are important for understanding the role of Greek pottery in trade and the economy (Sparkes 1996: 164–7; Cook 1997: 264; Boardman 2001: 153–67; Mannack 2002: 33–6; Stissi 2002: 288–332; Johnston 2006: 28–33; Oakley 2009: 612–13). The known exports of Greek ceramics, which are quite rich from the eighth century BCE onwards, only represent the tip of an iceberg, given that the surviving amount of Greek pottery is estimated to be less than 1% of the original output (this estimate relies on the surviving record of a special class of Attic vases, the Panathenaic amphorae, the production rate of which can be reconstructed with some accuracy (Stissi 2002: 27–30)). Trade in two ceramic categories has attracted most attention: painted fine wares and transport amphorae. In the last few decades the importance of trade in painted fine wares has been strongly debated. This material, previously considered a serious trade item, has been called "spacefiller" and "saleable ballast." Most scholars now hold that although fine pottery was not the main cargo of ships and was traded along other, more essential commodities, it still was widely exported and yielded considerable profit. Current research is aimed at understanding trade by comparing the distribution patterns of specific shapes and types or the output of different workshops and the popularity of certain scenes over different regions and/or over time; statistics and quantitative analysis are instrumental in this respect (Boardman 2001: 293–96; Stissi 2002: 325–32). Transport amphorae have received less attention, but they offer more reliable evidence for trade and the economy than fine wares in that they were not traded per se but for their content, which involved a broad range of foodstuffs, particularly wine and oil (Whitbread 1995). Shipwrecks found around the Western Mediterranean and the Black Sea are essential for understanding trade in Greek pottery.

Greek-painted pottery carries an amazingly rich array of scenes from mythology and everyday life but rarely shows specific historical figures and events (Sparkes 1996: 114–39; Boardman 2001: 168–243; Lissarrague 2001; Mannack 2002: 37–52; Oakley 2009: 613–17. See especially Figs. 5, 6, 7, and 8). Customarily, vessel shape/use shows no one-to-one link with the decoration, with few exceptions evidenced particularly in Attic pottery. Traditionally, scholarship has focused on iconography, that is, on identifying the individual figures shown and the entire composition through reference to literary texts (e.g., the gods on the wedding scene on the belly of the hydria of Fig. 5 or Herakles and the lion on the vase's shoulder). Lately, however, the distinction between images and texts has been emphasized and there are arguments suggesting that the

images are mostly based on stories which circulated orally, rather than on literary texts. Iconographic studies often chart the ebb and flow in the popularity of a subject, the changes in emphasis, and the external prompting which may have stimulated them. These stimuli may include theatrical plays (e.g., the scene on Fig. 8 is inspired by Aeschylus's play *The Libation Bearers*), monumental art, and even politics. For several decades, iconographic studies have been supplemented by iconological ones. According to iconology, the many scenes from everyday life rendered on Greek pots (e.g., in Figs. 6–7) are not photographic documents. These scenes, together with mythological ones, are social statements and constructs conveying ancient ideas and practices. The meaning, function, and cultural relevance of images on Greek pottery are therefore to be tackled by different approaches informed by anthropology (structuralism, poststructuralism) and literary studies (narratology, semantics).

Instrumental to this key issue, but also to the understanding of the social role of Greek pottery in general, is the historical, cultural, and functional contexts of the pottery (Sparkes 1996: 155–64; Oakley 2009: 599–601). Contextual information enables scholars to pose varied questions on the identity and the motivation of the users and to understand the different modes of ceramic consumption in sanctuaries, cemeteries, households, and marketplaces. This necessarily involves a fair treatment of the processes that formed an assemblage, the range of activities manifested, and the different wares represented. Past scholarship primarily focused on decorated pottery, while plain and cooking wares were heavily discarded, often before any sorting. In the last decades, excavation pottery is normally preserved (almost) in its entirety (with resulting problems in storage space), plain and cooking wares receive increasing attention, quantitative approaches gain ground, stratigraphy and associated finds are integrated in relevant research, and these developments allow for a deeper and broader understanding of ancient Greek ceramics.

Another line of inquiry, known as connoisseurship, regards the stylistic affinities of individual vases and their attribution to specific potters/painters (Sparkes 1996: 90–113, 153–55; Boardman 2001: 128–38; Oakley 2009: 605–7). This topic was first researched in the nineteenth century CE but came to be associated with the seminal work of Sir John Davidson Beazley on Attic pottery. Scholars first considered vases signed in the format "X drew/made me," but Beazley devoted his life to attributing thousands of unsigned Attic vases (such as those on Figs. 5, 6, and 7) to individual hands on the basis of the style of drawing. This exercise brought about a much deeper understanding of the Attic pottery industry and the development of Attic black-figure and red-figure. Beazley's method has provoked much debate in the last two decades. Critics stress the lack of an explicit methodology in Beazley's work and the subjectivity involved in attribution studies. Supporters have sought to define the inspiration for and the technicalities of Beazley's method, emphasizing that his attributions do not rely on few or random details, but on systems of rendering human anatomy and secondary ornaments (the debate is summarized in Oakley 2009: 605–7). This line of inquiry remains popular with scholars working on pottery from Attica and, to a lesser extent, Corinthia, Laconia, and South Italy, mostly dating from the late eighth to the fourth century BCE. Comparable research is centered on ceramic shape and the identification of potters through the study of the fine details of the profile of vessels.

Much research on Greek ceramics is dedicated to the compilation of catalogues and databases or relies on them (Oakley 2009: 601–4). Catalogues are part of a long and persisting tradition in the study of Greek pottery, going back to the days of Sir William Hamilton and the work of Otto Jahn (see above). Catalogues of excavation and particularly museum pottery form a particularly prolific type of scholarship, which is dominated by the monumental series *Corpus Vasorum Antiquorum* (CVA). This long-term project (ongoing since 1922) currently encompasses 350 volumes publishing tens of thousands of vases, most of which are Greek, particularly Attic black- and red-figure. This material can also be researched through the on-line database of the Beazley Archive in Oxford. Originally based on the work of Beazley,

the archive has steadily grown to include more than a quarter of a million photographs. A similar project for South Italian figured vases, the Trendall Archive (named after Arthur Dale Trendall, an expert on the subject), is housed at La Trobe University in Melbourne.

During the last two decades the reception of Greek vases has emerged as another key issue (Nørskov 2002; Oakley 2009: 617–9). This development is related to the growing attention devoted to the history of archaeology, the high prices paid for Greek vases in the art market (occasionally exceeding one million dollars), and the culmination of the problem of illicit antiquities. Scholarly attention has focused on the history of collecting Greek vases, the impact of these vases on modern and contemporary art, the ethics and practice of trade in antiquities, and their repatriation.

Future Directions

On-line publication of data and research, computer vision and pattern recognition, and digital applications in general are in the forefront of current developments in Greek archaeology. The potential of these tools for facilitating accessibility and cutting down cost are increasingly being appreciated by scholars working with Greek pottery, most notably by curators of vase collections. On-line databases, particularly the Beazley Archive in Oxford (www.beazley.ox.ac.uk/index.htm), have proved very useful for pottery studies. Before long, existing databases on ceramic fabrics will also appear on-line to facilitate discussions over provenance. Also, studies of provenance will increasingly make use of the range of analytical techniques outlined above, the application of which to Greek pottery of the first millennium BCE currently remains limited. Likewise, some of those techniques will be used to explore further the technology of ancient Greek pottery and fully document, for example, that wheel throwing was only one of several production techniques used widely.

Another direction, currently underexplored, but particularly promising regards the coverage of the full ceramic record of excavated assemblages, which is normally not limited to fine painted wares, but includes coarse and plain wares. Making the most out of the vast amount of pottery collected in excavations and surface surveys, and generally considered as undiagnostic, remains a major direction for future research. Likewise, there is an urgent need for balancing the Atheno-centric character of Greek pottery studies by further analysis of regional variation as well as for traditional and interdisciplinary research on the modes of stylistic dissemination.

Lastly, potentially revolutionary for the chronology of Greek (and other) ceramics is the novel dating technique of rehydroxylation (RHX). The technique relies on the fact that fired clay immediately begins to chemically react with moisture from the environment and thus increases in weight. Estimating the rate at which any ceramic piece absorbs moisture is the key for establishing its date of production. By 2011, experiments conducted on late antique to modern pottery had shown the potential of the technique, which remain to be explored with reference to ancient Greek pottery as well.

In conclusion, ancient Greek ceramics remain a major field of research for Classical and Mediterranean archaeology and an invaluable source of information for the study of the ancient world. The centuries-old fascination of scholars, collectors, and the wider public with Greek vases remains strong.

Ceramics, Roman Imperial

Abigail Crawford
Department of Archaeology, Boston University, Boston, MA, USA

Introduction

For an introduction to Roman ceramics, see the entry on "▶ Ceramics: Roman Republican and Early Principate" in this encyclopedia.

This entry covers Imperial Roman ceramics, which are generally considered to date from the last quarter of the first century BCE to the fifth century CE. As with Republican ceramics, there are subcategories of coarse wares and fine wares. What changed in the Imperial Period, however, was that Roman ceramic production experienced a degree of pan-Mediterranean standardization and production that had not been seen in the Republican period, especially with regard to *terra sigillata* (Fig. 1). It was in the Imperial period that Rome reached its greatest geographic extent and controlled all of the shores of the Mediterranean basin. The widespread distribution of ceramic wares speaks to the near universality of Roman material culture, while more local types highlight the local traditions that developed prior to or as a result of Rome's conquests.

Definition

Due to the widespread nature of imperial ceramics and the fact that they are studied by scholars from the many modern countries which composed the Roman diaspora, each type tends to have at least one alternate name, if not more. The English name is used here whenever possible for the sake of consistency. Alternate names are also listed. Unless otherwise specified, each of the following wares was produced throughout the Empire.

Ceramics, Roman Imperial, Fig. 1 Terra Sigillata at Museo della Città, Monte Porzio Catone. (Photo taken by author)

Coarse wares are defined as having a relatively rough fabric, with many inclusions and little to no decoration or surface treatment. These wares were durable and, for the most part, utilitarian. The fabric of fine wares generally was levigated to a greater degree and thus had fewer inclusions. These wares were often slipped or decorated and tended to be used as table vessels rather than cooking, transport, or storage vessels.

Coarse Wares

While fine wares tended to have finite production locations and periods of production, coarse wares were produced throughout the Roman Empire, both geographically and temporally. Since specific forms are not discussed, specific dates and production locations are not indicated underneath each type. For more detailed discussions of common wares, see the entry on "▶ Ceramics: Roman Republican and Early Principate" in this encyclopedia.

Cookware: Ceramica Comune, Ceramica Da Fuoco, Cerámica De Cocina, and Ceramique Commune

This is the name given to ceramics that were for use on the fire. They were typically produced and distributed locally, although some cookwares,

such as African cookware, were distributed throughout the Mediterranean beginning during or before the first century BCE. Cookware tends to have more and larger inclusions, which served to temper the ceramic and prevent it from exploding when heated. Common forms are pots, casserole dishes, lids, and pans. Cookware shapes did not vary significantly over time and are, therefore, somewhat difficult to date. Unfortunately, this difficulty has led many scholars to avoid studying them altogether. Typologies have been created, but ceramicists debate the precision with which the wares can be dated.

Tableware: Ceramica Comune and Ceramica Da Mensa

Tableware is a controversial category, since fine wares are often considered to be tablewares. Here tableware is taken to mean coarse or common wares used on the table. Fine wares are treated separately. Tableware often appears similar to cookware, but is made in different shapes and with slightly less temper. It was primarily intended as a utilitarian serving ware. As with cookware, it was largely produced and distributed locally. Forms include jugs, plates, bowls, basins, and cups. The same dating problems that plague cookware also make it difficult to date tablewares.

Amphorae

These transport vessels were primarily intended for sea transport. Their shapes and sizes varied depending on their cargo. Common cargoes include wine, olive oil, and fish sauce (*garum*). Less common cargoes were fruits and alum.

The production areas of some types of amphorae have been identified either through *tituli picti*, kiln excavations, or analysis of the locations of increased amphora type densities. *Tituli picti* – labels that are painted on the neck or shoulder of the vessel – typically recorded the weight of contents, the official in charge of weighing, and the geographical area of the amphora content's production. At first glance, *tituli picti* would seem extremely reliable for identifying production sites, but not all amphorae retain their *tituli picti*, not all amphorae had *tituli picti*, and *tituli picti* only indicate the production site of the amphora's contents, not the amphora itself. Kiln excavation is the most accurate method for determining amphora production centers, but for many types of amphorae, no kilns have been excavated. Finally, by mapping the densities of particular amphora types, scholars have postulated sources for particular types of amphorae. This method is less reliable than the preceding two primarily because density maps can be more indicative of where a particular area's amphorae were distributed rather than produced.

Nevertheless, by identifying amphora production sites and examining density maps, it has become possible to reconstruct trading patterns across the Mediterranean. While Greco-Italic amphorae were very common during the fourth to second centuries BCE, Baetican, North African, and Eastern amphorae became more common in the first four centuries CE. Amphorae are regularly found at sites on land, but they are also quite commonly discovered at the sites of ancient shipwrecks. These shipwrecks have contributed substantially to our knowledge of trade routes and practices. Following their primary use, amphorae were often reused for shipping, construction, as funnels, and as children's sarcophagi, among other things (Peña 2007).

The largest singular context of amphorae discovered thus far is Monte Testaccio in Rome. This site was a refuse dump for transport ships unloading on the Tiber River from the late first century BCE until the 260s CE (Peña 2007). The hill consists primarily of Dressel 20 amphorae, which were used to transport oil from Baetica, but North African amphorae have also been found there. Archaeologists regularly find *tituli picti* and amphora stamps on the amphorae, thereby allowing for a better understanding of the organization of both the government-run *annona* system and the commercial oil trade.

Several different amphora designations exist: Dressel (primarily from the Iberian Peninsula), Lamboglia, LRA (Late Roman amphorae), and Keay, to name a few. Some series are named for the scholar who studied them, others are named for their type sites, and still others are named descriptively (carrot amphora, micaceous water jar, etc.).

Dolia

Dolia (sg. *dolium*) were massive vessels used for storage or agricultural processing (e.g., fermentation). These pots, typically between 4 and 5 ft tall and equally wide, were handmade with coils or slabs. They were typically sunk into the ground, to prevent damage and to limit environmental effects on the contents of the *dolium*. It is clear from the prevalence of mends to these pots that they were expensive and difficult to replace. Nevertheless, when they did break, they could be reused either as basins or ovens. For a brief period of time, *dolia* were used in so-called cistern boats, but this transport method was discontinued shortly after its inception, perhaps because it was much riskier than transporting amphorae. Notable cistern-boat wrecks are La Giraglia, Petit Conglué, Ile Rousse, and Diano Marina (Marlier and Sibella 2002).

Mortaria

Mortaria were basin-type bowls that were used for grinding food. These vessels were wheel-made and had large, hard inclusions that would allow for more effective tearing and grinding. Typically the fabric of the interior surface of these vessels is worn away, leaving a rough surface of inclusions. There is often a pouring spout at some point along the rim of the vessel.

Lamps

Used for lighting and/or decoration, lamps range in size from that of one's palm to larger and more ornate pieces with multiple spouts for wicks (Fig. 2). These objects were typically made from molds and often featured decorative motifs in the discus. Common subjects were plants and animals, games and races, gods, or erotic scenes. While olive oil would have been the primary lamp fuel, other vegetable oils were also used. Loeschke, Broneer, and Bailey established the standard forms for lamps in the early twentieth century (Bailey 1980).

Fine Wares

Fine wares are the ceramics that Roman archaeological excavations tend to rely on for stratigraphic dating. The evolution of most types and forms has been meticulously studied, particularly for *terra sigillata* throughout the Empire. Specific dates and production sites are available for these wares, which rarely had the consistent forms or temporal span of coarse wares.

Terra sigillata – Samian ware, Arretine ware
Produced: 50 BCE–180 CE
Location: Empire wide, especially Gaul, Hispania, and Italia

Terra sigillata is also commonly referred to as Samian or Arretine ware. The ware is easily identifiable by its glossy red, orange, or brownish slipped surface. The fabric is very fine, with few and minute inclusions. The slip was rich in iron and fired in an oxidizing atmosphere, which created the characteristic bright gloss. The successor to black gloss, *sigillata* evolved from pre-sigillata, which utilized black gloss forms and a duller, less even red slip. Some argue that *terra sigillata* also evolved from Italo-Megarian ware, which was molded but was unslipped. As with black gloss, similarities have been drawn that connect *terra sigillata* forms and decorations with forms and decorations seen on more expensive metal vessels.

For standardization and efficiency's sake, *terra sigillata* was made within a mold on a wheel. The molds were decorated beforehand with stamps and/or makers' marks. Not all pieces were decorated, however, and not all decorations were molded. In some instances, rouletting was used along the rims of the vessels, and in other instances, barbotine was applied to the vessels' sides or rims prior to firing. Decorative stamps were floral or figural in nature. Makers' marks applied to the vessels have been noted as belonging to the workshop owner, the mold maker, or the potter. Some vessels have been found with multiple marks on them. Oftentimes a mark integrated into the mold is taken to be the mold makers, while a stamp on the base or tondo of the pot probably indicated the workshop owner.

Forms were primarily for use on the table – cups, bowls, and plates – with occasional *terra sigillata* lamps.

The production of *terra sigillata* began in Italy toward the end of the first century BCE. A major production site was first identified in the area around Arrezzo, hence "Arretine ware." This, however, is misleading since there were many areas of *terra sigillata* production all across the Mediterranean. In addition to Arrezzo, some major production sites were Pisa, Ostia, and Pozzuoli in Italy, La Graufesenque and Montans in France, Rheinzabern in Germany, and Tricio in Spain. While each production center experienced different periods of popularity, all *terra sigillata* had largely stopped being produced by the third century CE, when African red slip had replaced it.

Terra sigillata africana is classified as African red slip, since it is not technically produced in the same manner as *terra sigillata*.

Eastern sigillata – Cypriot sigillata, Çandarli ware
Produced: 150 BCE–300 CE
Location: Asia Minor

Eastern *sigillata* A was produced in North Syria during the late Republican and early Imperial periods. Like *terra sigillata*, it has a red slip, but the fabric of the vessel is much lighter than that of terra sigillata. Later forms of ESA were similar to those of Italian *terra sigillata*.

Eastern *sigillata* C, or Çandarli ware, was produced around Bergama and Çandarli during the first and second centuries CE. Some examples have been found in fourth century deposits, but it is not clear whether they were produced in the fourth century or are residual. The fabric was pale brown to light red with an orangey slip.

Thin-walled ware – pareti sottili, paretes fines, parois fines, and paredes finas
Produced: 200 BCE–300 CE
Location: Began in Italy, spread to the provinces

This ware is easily recognizable by its refined fabric and very thin walls. It is hypothesized that this tableware was a ceramic imitation of metal and glasswares. Thin-walled ware was made both on wheels and in molds. Its shapes are typically cups and mugs, either plain or decorated (Fig. 3). Beginning in the Augustan period, decorations included barbotine, sabbiatura (sand applied to the vessel's surface prior to firing and before slipping), rouletting, or incision. Also beginning in this period was the application of slip to the inner and/or outer surfaces of the ware, perhaps in order to increase its impermeability. Prominent workshops were in Chiusi, Aquilea, Sutri, Torrita di Siena, Syracuse, and Cremona in Italy, and Lyon and Lezoux in Gaul.

By the second half of the first century CE, the number of vessel forms had diminished. The vessels' fabric gradually became less refined, its walls thicker, and eventually it was very close in form and fabric to common ware (Guerrini and Mancini 2007).

African Red Slip – Terra sigillata africana
Produced: 80 CE–750 CE
Location: Modern Tunisia

Also known as *terra sigillata africana*, this ware originally imitated the forms and decorations of terra sigillata from Europe. By the second century, however, African red slip shapes began to be made broader and shorter, perhaps allowing for easier stacking and transport. Major production

Ceramics, Roman Imperial, Fig. 3 Thin-walled ware, Museo Archeologico Nazionale di Cosa. (Photo taken by author)

sites were located in Tunisia at el-Djem, Carthage, and Raqqada. While most African red slip forms were moldmade in the same manner as *terra sigillata*, some larger vessels were thrown onto upside down molds beginning in the fifth century CE. Hayes proposes this method allowed for application of feet to the vessels while they were still on the mold. He also points out that internal stamped decoration would have been part of the mold.

Fabric colors vary from orange-red to brick-red, and similarly colored, but slightly darker slip. The slip of African red slip is not as bright or shiny as that of *terra sigillata*. Decorations were typically stamped, appliqued, or rouletted.

African red slip ware is taken as the prime indicator of late Roman occupation in both archaeological surveys and excavations.

Historical Background

Beginning in the fifteenth century, *terra sigillata* caught the eye of antiquarians and researchers. Its durable nature, figural designs, and bright sheen ensured that it was easily spotted whenever earth was moved. Early finds were often only briefly mentioned in journals and were usually not illustrated (Tyers 1997).

The modern study of Roman imperial ceramics began with Hans Dragendorff's 1895 publication "Terra Sigillata: Ein Beitrag zur Geschichte der griechischen und römischen Keramik" in *Bonner Jahrbüchen*. In this article, he systematically described and drew Roman ceramic forms from continental Europe. His work is still used for identifying and dating *terra sigillata* forms across the Mediterranean. After Dragendorff's work was published, other scholars became more systematic in their identification and illustration of Roman wares. Among these scholars were Howard Comfort and August Oxé, who, during the course of the early twentieth century, published extensively on *terra sigillata* stamps and vessel forms. Their detailed study of stamps furthered the understanding of workshop organization. While these early studies were focused on forms and decorative motifs, more recent studies have come to focus on the organization of ceramic production, questions of supply and distribution, and the role of fine and coarse ceramics in Mediterranean trade.

Unlike fine wares, amphorae have few aesthetic qualities to distract from their functional aspects. Thus, amphora studies have traditionally concentrated on the vessels' chronologies, production centers, distribution, and economic significance. Heinrich Dressel was the first to create a typology for amphorae. His 1899 effort, which appeared in the *Corpus Inscriptionum Latinarum*, was followed by Siegfried Loeschke (*Keramische Funde in Haltern: ein Beitrag zur Geschichte der augusteischen Kultur in Deutschland*, 1909), and some decades later by M. H. Callendar (*Roman Amphorae with an Index of Stamps*, 1965), M. Beltrán Lloris (Spanish amphorae, 1970), Riley (Benghazi ceramics, 1979), Laubenheimer (Gaulish amphorae, 1990, 1991, and 1992), Panella (1992), and others. Broader compendia on amphorae and their economic significance were penned by Peacock and Williams (1982) and Keay (1984).

Late Roman pottery was not extensively published until 1972 in John Hayes' aptly named *Late Roman Pottery*. This publication covers African, eastern, Egyptian, Gaulish, and assorted other wares known from later deposits.

Since computers and databases became easily accessible and common in the 1980s and 1990s, statistical analysis of ceramic quantities has blossomed. This has allowed for more detailed intra- and inter-site analyses of assemblages. Now, with the availability of Geographic Information Systems (GIS) software, it is possible to study ceramics not only quantitatively but also spatially.

Key Issues/Current Debates

For centuries archaeologists have looked to historical texts to explain ancient life. This often leads scholars to shape their material culture data to fit the literary sources. In the past two to three decades, there has been a distinct movement away from texts and toward the use of material culture to inform us about the past. The study of cultural interaction has benefited greatly from this new approach. While "Romanization" was previously thought to be a one-way process of cultural imposition, ceramic studies by Willis, Roth, and others have been used to show the opposite and draw conclusions about social and economic conditions of the Roman conquest (Millett 1992; Willis 1996; Roth 2007).

Following the rise of survey archaeology, archaeologists began to question the manner in which ceramic data collected from surveys could be interpreted. In survey archaeology's early years, the ceramics that appeared on the surface were taken at face value. All surveyors were presumed to have the same recovery rate, the extent of a ceramic spread was used to identify the size of a site, fine wares were recorded more frequently than coarse wares because of their greater visibility, and quantification (e.g., density and weight) was minimal. As survey archaeology became more methodologically refined and more intensive, the veracity of conclusions drawn from collected ceramics came under question.

One way in which scholars are tackling concerns about ceramic interpretations is by publishing not only their methodology but also the specific finds that were either recorded or collected. Such a transparent approach allows for other scholars to draw their own conclusions, but also makes it possible to compare sites that have been similarly documented. Such publications are ideal, but are by no means widespread as yet.

International Perspectives

In the United States, there is currently a lack of Roman ceramic courses for students who wish to specialize in the field, as well as a dearth of jobs for Roman ceramicists. This is likely a result both of limited interest in the field and of restricted opportunity for first-hand study. While schools in Europe often have access to collections that they can easily study, very few schools in the North America can say the same. Often the collections that they do have are fragmentary or poorly documented. University courses in North America tend to focus on Greek ceramics for their art historical value and spend little to no time on Roman ceramics or the role of ceramics in archaeological interpretation. From a researcher's standpoint, the most useful publications tend to be in Italian, French, Spanish, or German, although detailed English publications are becoming increasingly available.

Future Directions

Important to the furtherance of Imperial Roman ceramics studies, and Roman ceramics studies more generally, is the integration of Roman ceramics courses at the university level outside of Europe and increased publication in English by scholars. In order for this to happen, there need to be positive relationships between schools and European governments so that collections can be temporarily held and studied in the United States and elsewhere. To this point, European nations have been hesitant to allow material culture to leave their borders, perhaps out of a post-colonial fear that the objects will never be returned. In this age of accountability and mass media, however, it is unlikely that any foreign institution could hold another country's ceramic

collection indefinitely without massive outcry and the attendant legal ramifications.

In the field of survey archaeology, better publication of ceramic finds will not only back up archaeologists' conclusions but will also allow for contextual analyses and spatial distribution studies to be performed. The more information that is published, the easier it will be to draw meaningful comparisons between disparate geographical regions.

Additionally, increased comparison of survey finds to excavate material needs to occur on a more regular basis. Such comparisons may provide lead to more accurate interpretations of surface scatters.

Finally, ceramic data must be published and made available in order to make pan-Mediterranean site analysis and comparison possible. In addition to catalogs of relevant finds being published, syntheses of those ceramics should also be attempted. Publications such as Roth's show that ceramic data are useful not only for dating strata but also for understanding Roman identity and cultural change.

Ceramics, Southeast Asian and Chinese Trade

Tse Siang Lim
Spring Hill, QLD, Australia
School of Archaeology and Anthropology, Research School of Humanities and the Arts, College of Arts and Social Sciences, Australian National University, Canberra, ACT, Australia

Introduction

Ceramics have been in Southeast Asia since the early Holocene. The earliest, best-dated examples

in Mainland Southeast Asia are cord-marked, net-marked, burnished, appliquéd, and incised Hoabinhian earthenware pottery sherds found at the Spirit Cave in north-western Thailand, dated to approximately 8,400 years old. In comparison, the earliest known earthenware ceramics found in the Malay Archipelago consist of plain and burnished pottery recovered in East Timor dating to a horizon of 4,500–3,700 years ago (Solheim 2003).

The use of paddle impressions with basket- or cord-marked patterns, carved paddle impressions, cord marking, incising, burnishing, and slipping are among the oldest pottery decorative techniques found in Southeast Asia (Solheim 2003). This early decorative pottery tradition is thought to be distributed across Southeast Asia by the "Neolithic Nusantao Maritime Trading Network" (Solheim 2006). Lapita pottery, as well as Solheim's Sa-Huynh-Kalanay and Bau-Malay pottery are thought to be derived from this Neolithic tradition, with Sa-Huynh-Kalanay ceramics believed to be gradually replaced by those of the Bau-Malay tradition during the first millennium CE in island Southeast Asia (Solheim 1990).

The Bau-Malay pottery rubric claims that all carved paddle impressed earthenware in the southern Philippines, west Borneo, western Indonesian islands, and the Malay Peninsula were produced from 700 CE onward. "Tanjong Kubor" ware is the only other proposed precolonial (700–1500 CE) major pottery style in the Malay Archipelago which affiliates earthenware ceramics from sites in Brunei, south Philippines, Sarawak, and Johor Lama. Bellwood and Omar (1980: 173) have argued that "the distribution pattern [of Tanjong Kubor ware] is related to the development of the Malay language as a trading language in those areas where it is most commonly spoken today."

Unlike their low-fired earthenware cousins, high-fired stoneware, and porcelaneous ceramics have had a relatively shorter life span in Southeast Asia. The Vietnamese, having had a long history of political and cultural interactions with the Chinese beginning as early as 111 BCE, started to produce stoneware ceramics approximately 2,000 years ago. However, it was not until the ninth century CE that the technique of producing high-fired pottery was first developed indigenously by the Khmers in Southeast Asia (Miksic 2009a). "Khmer ware," as these first Southeast Asian stoneware ceramics are now called, is believed to be a result of the diffusion of Chinese pottery manufacturing technology. It has been observed that Khmer ceramics share many similarities with contemporaneous products from the Xicun (西村 Xī Cūn) and Chao-an (潮安 Cháo Ān) kilns in the southern Chinese province of Guangdong (广东 Guǎng Dōng) (Rooney 1984; Brown 1989). Southeast Asian potters did not achieve the required temperatures to produce true porcelain, an accomplishment solely achieved by the Chinese during the Tang dynasty (618–906 CE). The Chinese held a monopoly on porcelain until the Japanese and Germans discovered the technique in the seventeenth and eighteenth centuries (Yeo and Martin 1978). Nonetheless, Thai and Vietnamese potters were able to produce high-fired, glazed ceramics resembling Chinese porcelain – such as Thai celadon and Vietnamese underglaze cobalt blue – and exported them across the region between the fourteenth and sixteenth centuries.

Definition

Precolonial Southeast Asians acquired Chinese stoneware and porcelain ceramics through a long established maritime trading network with China, commonly referred to as the Nanhai (南海 Nán Hǎi or "South Sea") trade (Wang 2007). Chinese ceramics from the Western Han period have been found in south Thailand (Miksic 2009b), thereby suggesting the existence of a well-established trading network between both regions as early as the first to second centuries CE. However, Chinese porcelain was first recorded as a maritime trade item only during the Song dynasty, a period where foreign trade flourished under the incentive to secure additional revenue, especially after their defeat by the Khitan nomads in 1126 CE (Miksic 2009a).

The export of Chinese stoneware and porcelain ceramics into Southeast Asia generally occurred at two levels. Firstly, lower quality high-fired ceramics were produced and exported from the southern "provincial" or "folk" kilns (民窑 Mín

Yáo) of Guangzhou (广州 Guǎng Zhōu) in Guangdong (广东 Guǎng Dōng) province and Quanzhou (泉州Quán Zhōu) in Fujian (福建 Fú Jiàn) province. Secondly, "national" or "imperial" kilns (官窑 Guān Yáo) at Jingdezhen (景德镇 Jǐng Dé Zhèn) and Jizhou (吉州 Jí Zhōu) in Jiangxi (江西 Jiāng Xī) province, Longquan (龙泉 Lóng Quán) in Zhejiang (浙江 Zhè Jiāng) province, and Dehua (德化 Dé Huà) in Fujian province produced ceramics of higher quality and value (Heng 2009).

Evidence of this early maritime trade is illustrated by numerous shipwrecks found in Southeast Asian waters. The Belitung shipwreck, found off the coast of Java, held a large cargo of Chinese Changsha ceramics dating to the ninth century (Flecker 2011), a period when Chinese ceramics were believed to be exported at a voluminous level for the first time. The Turiang, a fourteenth century (c. 1305–1370) shipwreck located off the eastern coast of the Malay Peninsula, was found to have set sail from Guangdong with a cargo containing monochrome, brown- and green-glazed stoneware vessels made in the provincial kilns of Guangdong as well as green-ware vessels from the imperial kilns in Zhejiang. High-fired Thai (Sukhothai, Sawankhalok and Suphanburi) and Vietnamese ceramics, the bulk of the ship's cargo, were recovered as well. Other shipwrecks such as the Nanyang (c. 1380), Longquan (c. 1400), Royal Nanhai (c. 1460), Xuande (c. 1540), and Singtai (c. 1550) also held an assortment of high-fired Chinese, Thai, and Vietnamese ceramics (Brown 2009), thereby depicting an intricate level of inter- and intra-regional trade.

Chinese ceramics were not only simply imported commodities, but also functioned as media of exchange between Chinese and local merchants in the conduct of trade in precolonial Southeast Asia. Southeast Asian societies adopted monetary standards based on "a directly measurable quantity" of highly valued substances or commodities (Wicks 1992: 301). When the Song court banned the export of precious metals such as gold and silver as well as copper cash in 1127, 1133, 1175, and 1219, porcelain ceramics became a commodity-substitute in overseas maritime trade and transactions. Ceramics were specifically named as one of the products to be used in place of gold and silver during the 1219 ban (Heng 2009). In exchange, Chinese traders received from Southeast Asian merchants various aromatic products, spices, and precious items such as pearls, ivory, rhinoceros horns, and other tropical produce needed to satisfy the Chinese market.

Key Issues/Current Debates/Future Directions/Examples

Ceramic artifacts are ubiquitous throughout Southeast Asian archaeological sites, but as a field of study, ceramic analysis in Southeast Asia remains in its infancy and is confined mostly to the realms of ethnography and art history. The importance of ceramics in understanding ancient cultures, long established by generations of archaeologists in other parts of the world, has been overshadowed in Southeast Asian archaeological studies by the structural and monumental remains found across the region, and the pervasiveness of historical narratives reconstructed from epigraphic and textual sources. Consequently, archaeological research in this region remains largely oriented toward the study of major orthogenetic precolonial urban centers largely defined by the presence of architectural, statuary, and epigraphic remains (Miksic 2000). Conversely, there are relatively few archaeological studies of household architecture and status goods which might reveal "evolving wealth differentials and social stratification in prehistoric and early historic period societies" have been conducted (Junker 1999: 151).

Nonetheless, the efforts of archaeologists over the last few decades have produced considerable, albeit disparate, data and literature that have advanced the knowledge of socioeconomic, trade, and settlement patterns of precolonial societies in both mainland and island Southeast Asia. In particular, research on ceramics has demonstrated that greater socioeconomic and political complexity in precolonial Southeast Asian

societies is typically accompanied by the development of a "political economy" where certain goods function as a "material fund of power" which is used to "reinforce social inequality and political authority," with hereditary "elites" controlling the specialized production and exchange of such goods (Junker 1994: 3). Ceramics were often used in precolonial Southeast Asia as a measure and indicator of social rank distinction. Stylistic, technological, and distribution analyses of decorative earthenware pottery found in the Philippines have also suggested that some decorative styles could have been iconographic representations of inter-chiefly elite alliances or shared identity in the late prehistoric and protohistoric period (Bacus 2003). As trade routes were established between Southeast Asian and Chinese markets over the centuries, Southeast Asian elites found a new source of high-quality and beautiful ceramics that they did not have the technology to produce (Heng 2009). Imported Chinese ceramics, such as small vessels with lids, came to be considered a luxury suitable for use only by the Khmer nobility in the eleventh century (Miksic 2009b). Chinese porcelain, among other exotic luxury goods, also became "key symbols of social status and political power" together with indigenously manufactured prestige goods for the Philippine chiefly elite (Junker 1999: 183).

Ceramics can also be used for stratigraphic dating in most Southeast Asian archaeological sites. It is possible to use thermoluminescence (TL) dating to determine the absolute date when the ceramics were fired, but its results will contain a range of error usually between ±90 and 110 years. This range of error is too great for TL dating to be of much use for most precolonial Southeast Asian sites which normally have a narrow life span between one to three centuries. Relative dating through established Chinese ceramic typologies, in particular, is a more accurate alternative. The stylistic features of these ceramics – such as the type of decorations, motifs, and glaze patterns – are distinctly associated with specific dynastic periods in Chinese history. The recovery of Chinese ceramics in situ not only allows for the successful dating of other material cultural remains in the same stratigraphic layer, but also reconstruction of the entire occupational sequence at a well-excavated site.

The precise provenance for each ceramic sherd in terms of the exact region, kiln site of origin as well as period of manufacture, is dependent on comparisons with other ceramics. However, the existing knowledge of ceramic production and distribution is still far from complete; research on ceramic kiln sites in Southeast Asia is relatively underdeveloped, and despite a documented history of Chinese ceramic connoisseurship, there is a paucity of reliable information that can be gleaned from Chinese literary sources on the ceramic industry. Consequently, a detailed chronology for the majority of Chinese and Southeast Asian trade ceramics has not been established (Brown and Sjostrand 2004). Regional studies that compare the physical characteristics, forms, decorative styles as well as archaeological and historical contexts of ceramics have the potential to provide conclusive evidence in the identification of ceramics recovered in the region.

The study of Southeast Asian earthenware ceramics in particular has largely been overshadowed by that of its more aesthetically attractive high-fired ceramic cousins. Although earthenware sherds make up the majority of artifacts recovered from archaeological sites in the region, they still remain "neglected in reported finds, analyses, and published references" (Rooney 1987: 1). The lack of publication in Southeast Asian earthenware studies was still endemic in the region as late as 2003 (Miksic 2003). In an effort to remedy the situation and create a regional archaeological framework of earthenware analysis, Miksic (2003) seminal study *Earthenware in Southeast Asia* encompassed the latest earthenware research across the major Southeast Asian nations. To date, it remains the only publication which focuses solely on earthenware ceramics in Southeast Asia. At the same time, ethnographic records of traditional or rural earthenware potters remain few because research is narrowly concentrated on selected Southeast Asian ceramics which are

"recognized as having great cultural and monetary value, such as the famous prehistoric Ban Chiang pottery and the high-fired celadon wares of Sukhothai and Sawankhalok" (Shippen 2005: 11). Consequently, any identification and analysis of earthenware ceramics can only rely on comparisons with the few existing published catalogs and be informed by the existing archaeological record and historical context that surrounds these artifacts.

Ceramics: Colonoware

Laura J. Galke
The George Washington Foundation,
Fredericksburg, VA, USA

State of Knowledge and Current Debates

Description

Colonoware is not a formal ceramic type and epitomizes cottage-level fabrication. Idiosyncratic in the execution of production, methods, marketing, and techniques for surface embellishment make generalizations impractical. No definition of colonoware exists that applies to this ceramic in all places and at all times. That being understood, the following description provides a suitable introduction to this dynamic, interpretively rich ceramic.

Colonoware [also colono ware, colono, Colono-Indian ware, Afro-Caribbean ware] was a locally produced, low-fired, unglazed coarse earthenware ceramic found in European colonial contexts that was hand-formed either by coiling, pinching, or the slab technique (Figs. 1 and 2). It was rarely wheel thrown. Early, definitional examples of the ware exhibited Old World vessel forms, including (but not limited to) chamber pots, teapots, candlesticks, porringers, pipkins, and mugs. However such manifestations were atypical, and bowls, jars, and smoking pipes were more commonly recovered forms. The term has also been employed to refer to locally produced, handmade beads. Its local level of production places the field of historical archaeology in a crucial position to identify this ware and to produce the data essential to understanding the sociopolitical environments of its construction and use. If a ceramic could be chosen as the emblem of historical archaeology, it would be colonoware.

The New World production of Old World vessel forms and colonial migrant use of colonoware represented the material embodiment of international, multicultural contact. Colonoware manifested elements of multiple, competing cultural traditions and reflected the challenges that colonization presented and imposed upon the communities involved. For this reason it is sometimes referred to as a "creole" or "hybrid" ware, because it blends elements of what were conventionally thought of as culturally distinctive attributes.

Analyzing colonoware is as engaging as it is challenging. Determining how this ware reflects the social lives of its creators and consumers is not only a goal of historical archaeology but speaks to the discipline of anthropology. How are identity, culture, and society reproduced in material ways – and at different scales – and how do political and social practices act to promote or constrain material production and consumption?

In the United States, colonoware has been discovered from the Chesapeake region southward into Florida and westward into Tennessee and Kentucky (Ferguson 1992: 35–37). The Spanish colonial southwest region of the United States and the Caribbean each preserve an independent tradition of colonoware (Deagan 1987, 2013; Dyer 2010, Hauser 2013; Peelo 2011). In British colonial North America, the ware is often found in contexts associated with enslaved laborers, but this pattern is by no means universal. Its spatial distribution across North America is not uniform: archaeological investigations have recovered large proportions of colonoware in ceramic assemblages on plantations in South Carolina and Florida, but much lower quantities characterize the assemblages of the Middle Atlantic region and Georgia (Espenshade and Kennedy 2002: 212, 216, 224; Ferguson 1992: 7–9, 35–37; Galke 2009: 306–307).

Colonial law and cultural practices imposed upon New World inhabitants varied between European powers. Depending upon the time period and region under study, these policies sometimes directly, sometimes incidentally, influenced New World manufacturing, proselytizing, and social relationships in general. Despite these rules, multiethnic households were formed and in some environments even thrived (Loren 2000). The vagaries of these rules placed constraints or created opportunities for colonoware production that vary from colony to colony and

Ceramics: Colonoware, Fig. 1 Colonoware bowl fragment from the first quarter of the eighteenth century. (Courtesy The George Washington Foundation)

Ceramics: Colonoware, Fig. 2 Colonoware bowl rim fragment from Pohoke, Manassas National Battlefield Park, Virginia [Photograph by Laura Galke. Used with permission from the National Park Service, National Capital Region. Permission Pending]

from time period to time period. The degree to which colonoware represents any given ethnic identity in form, manufacture, and decoration was determined by the evolving, dynamic socio-political environment in which it was produced.

Archaeological data indicates that the earliest colonoware can be found in early-sixteenth-century Spanish settlements in the Caribbean, Mexico, the Southwestern United States, and Florida. These areas developed a colonoware

tradition independent from the seventeenth-century Chesapeake region and eighteenth-century American South (Chodoronek 2013: 57, 65; Cobb and DePratter 2012: 447, 452–453; Deagan 1987: 103–104, 270; Dyer 2010; Ferguson 1992: 18–22, 44–47; Noël Hume 1962; Pogue 2017: 15). In the Middle Atlantic region, it appears that colonoware manufacture and use continued at least until the turn of the nineteenth century. In some communities, it appears to be produced until the conclusion of the American Civil War (Galke 2009). In portions of the Caribbean, colonoware production continues.

The culturally pliant nature of colonoware was reflected in Noël Hume's initial encounter with this ware. In his 1962 publication, he introduced it to the field as "Colono-Indian ware." Noël Hume intended the term to be limited to burnished wares that were explicitly *produced* by Native American Indians, that *exhibited* European vessel form, and that were *used* by enslaved Africans (Noël Hume 1962: 5, 7, 13, emphasis mine). In the Virginia Tidewater region where it was first recognized, this pottery exhibited traditional, American Indian temper including shell and red ochre (Noël Hume 1962: 3). In the same year, Charles Fairbanks (1962) also described his encounter with colonoware. Like Noël Hume, Fairbanks credited its production to local American Indians and emphasized the ware's European-inspired vessel forms.

When considered across its full continental range, colonoware temper varies considerably (Fig. 3). Since Noël Hume's publication, colonoware has been encountered in a variety of contexts across time and space. Its description remains varied and has broadened. Noël Hume's article is worth reviewing, if only to appreciate how much the colonoware designation has drifted from his original analysis. Decades later, Deagan (1987: 103–104) broadened this coarse earthenware's definition to describe colonoware as New World-produced pottery that was used within colonial households.

Regardless of the broad geographical region under consideration, it seems that especially during the earliest decades of contact in any given area – whether it was the sixteenth-century Caribbean or the seventeenth-century Chesapeake – locally made colonoware in part fulfilled an urgent need for pottery that was created when shipments of household wares from Europe were insufficient. In these contexts, Native American influence on colonoware production and use is evident and often the focus of research (Deagan 1987: 103, 1996, 2013; Noël Hume 1962). Later, enslaved African communities grew and contributed to evolving traditions of local pottery manufacture and use. Colonoware studies of these eighteenth- and nineteenth-century assemblages were inspired by the nature of colonial and/or plantation economies and their expressions of African American cultural traditions in a variety of media (Ferguson 1992; Loren 2000; Singleton

Ceramics: Colonoware, Fig. 3 Colonoware body sherds from the Henry House, Manassas National Battlefield Park Virginia, showing a variety of paste and temper [Photographs by Laura Galke. Used with permission from the National Park Service, National Capital Region. Pending]

and Bograd 2000; see also Cobb and DePratter 2012: 450).

Recent analysis of locally produced earthenware ceramics demonstrates that these finely potted tablewares became fashionable among consumers of a variety of ethnic backgrounds and even with elite households at Ciudad Vieja, El Salvador (Deagan 2013: 264–165). Decades of colonoware analysis and research suggest that the ability for potters to materially express ethnicity and class is constrained by broader social and political contexts. The study of colonoware has the potential to address dimensions of gender, class, economics, ethnicity, politics, and marketing at the local level.

Colonoware vessels incorporate features that analysts have attempted to attribute to specific ethnic groups with varying degrees of success. For example, the presence of a flat bottom was an attribute presumed to be European in derivation. Vessel forms such as bowls were deemed as having Native American or African origins, especially if the vessel lacked a foot ring (more commonly encountered in European or Asian vessels). Many of these assumptions remain problematic, as many identified "ethnic" characteristics could be found within the historical traditions of each of the groups under consideration. However, forms such as candlesticks, chamber pots, milk pitchers, and teapots, while not common, lack New World antecedents and could be confidently attributed to European and/or Asian influence.

As more data are accumulated, generalizations about colonoware use and distribution seem contingent, and the complex effects of material culture, class, gender, status, production, distribution, and use become increasingly apparent. The ware's cottage-level production and varying consumer base across time and space present analytical challenges that frustrate traditional explanatory paradigms. The degree to which this reflects the entangled meanings and use of this particular ware, or material culture in general, is worth considering. Context is crucial toward understanding this complex ware. Colonoware is best understood at the community level, and in discrete temporal units.

Colonoware Fabrication

The vast majority of colonoware vessels were slab- or coil-built, and not typically wheel thrown nor mold-made. They were usually fired at low temperatures (Espenshade and Kennedy 2002: 210; Ferguson 1992: 19, 27; Hauser and DeCorse 2003). Mold-made smoking pipes (Monroe and Mallios 2004: 69–70) and even wheel-thrown vessels (Deagan 1987: 103–104, 2013) provide rare exceptions to this hand-manufactured rule. Vessels are often described as having little or no temper, but this, too, is not consistent across broad geographic and temporal scales of analysis. Surfaces were often smoothed and burnished, and common forms include bowls and smoking pipes (Ferguson 1992). Table 1 provides online URL links to three-dimensional, scanned colonoware sherds from Virginia. Vessel forms such as bowls were conducive to a diet based upon soups and stews, which some scholars suggest reflected African food ways (Ferguson 1992: 90). Stews were also a clever choice for enslaved people who labored long hours and whose cooking methods and ingredients favored recipes that could simmer for a long period without a great deal of supervision.

The earliest published references to this ware credit Indigenous Americans for its manufacture (Fairbanks 1962; Noël Hume 1962: 3–4, 12). As the field of historical archaeology grew, its research goals expanded to include the examination of the lives of subaltern groups about whom little was written or known. As a result, site areas were excavated that produced more colonoware from a variety of contexts and time periods. The opportunity to study colonoware's variability across time and space was possible as never before. The assumption that the final users of colonoware were necessarily the producers of the ware was questioned by some.

In Eastern North America, the correlation of increased colonoware use with the expansion of the enslaved of labor (both American Indian and African laborers) led some scholars to argue that enslaved Africans were the primary producers – not just consumers – of colonoware (Chodoronek 2013: 64–66; Deetz 1988: 362, 1993, 1996;

Ferguson 1992: 9, 18). Furthermore, the fact that colonoware pottery increased just as population of Native Americans in any given area decreased provided circumstantial evidence that supported the association between enslaved labor and the manufacture of colonoware (Chodoronek 2013: 62–63; Deetz 1988: 365–366; Fennell 2011: 19–22, 25 Ferguson 1992: 35–37; Galke 2009: 303–304, 306–307, 316–318, 320–321). Furthermore, the greatest concentrations of colonoware tended to be recovered from sites and contexts associated with enslaved laborers, especially once the domestic spaces of planter and servant formally diverged after the 1660s (Deetz 1988: 365–366).

The spatial separation of the living spaces of free people from servants was a crucial development in the evolution of distinctive material signatures of status, a pattern routinely seen by archaeologists in housing, ceramics, and faunal remains. This began with indentured servitude and continued to develop with the establishment of slavery in the United States. The evolving distinction of living space began in the Chesapeake during the final decades of the seventeenth century, as slavery became institutionalized and an increasingly larger proportion of the laboring class was derived from enslaved Africans rather than indentured servants (Fennell 2011: 20).

Deeper in the American south, the paradigm for dissociating the living spaces of free planters from servants was well established by the time that plantation culture was imposed. In these areas, the enslaved made and used their pottery in forms and using methods that were influenced more by African traditions than European or Indigenous practices. These traditions were reinforced by the sustained contact between

members of these substantial diasporic communities of enslaved Africans on these comparatively immense work camps (Deetz 1988: 366; Ferguson 1992: 16–17, 84–92).

The people who produced colonoware vessels are not necessarily the ones who used them. Focusing upon nineteenth-century production in South Carolina, Espenshade and Kennedy (2002: 235) demonstrated that within the plantations they studied, a single colonoware potter could manufacture sufficient vessels for their entire community.

Hauser and DeCorse (2003: 71) claim colonoware is best understood as a ware that is associated with communities scattered by the African diaspora, but Galke's (2009) analysis of one postcolonial Virginia community is more nuanced. She suggested that at Manassas the ware was associated with Americans in bondage, since free families in the community rejected colonoware, whether of African or European descent. In that particular antebellum locality, ethnicity was not associated with colonoware as directly as enslavement.

Chesapeake Pipes

Smoking pipes were used to ingest herbal substances – most popularly tobacco – which were intended to be enjoyed through inhalation or swallowing. In the New World, smoking pipes, made from stone or fired clay, predate European contact by thousands of years. After contact, local production of these pipes became a minor industry, and the degree to which these pipes represented colonoware or the continuation of existing American Indian pipe production is debated.

Some locally produced pipes were hand built while others were molded. American Indians, Europeans, and Africans all produced these useful forms, sometimes for their own use but also for sale to other communities. In the Middle Atlantic, early scholarship suggested that pipe production appeared to correlate with interruptions in global shipping, a consequence of Old World political strife (Deetz 1993, 1996; Henry 1979: 15–18). More recently, Monroe and Mallios (2004) document a thriving Jamestown-based production of both molded and handmade colonoware pipes in the seventeenth century. While locally made pipes were often temporally associated with the contact era, locally produced, reed stem colonoware pipe manufacture continued in some communities at least through the antebellum period (Galke 2009).

Decorated and Marked Colonoware

Vessels were rarely decorated, but, when embellished, incising, punctuating, or everted rim treatments were most popular. In Spanish colonial contexts, they were occasionally painted. The motifs employed on these vessels reflect the hybridity of the communities they served (Deagan 2013).

One motif that has inspired considerable debate resides in the form of a two intersecting lines (one horizontal, one vertical) that cross at a 90° angle in the middle of their respective segment lengths. Occasionally these two crossed lines are framed within a circle or square. These particular marks were noted on the base of some colonoware vessels. These symbols were often incised, but stamped versions were also identified (Agha and Isenbarger 2011: 185–186; Joseph 2016). The similarity between this symbol and the Kongo Cosmogram (*dikenga*) inspired some scholars to suggest that such marked vessels possessed spiritual, ritual, or medicinal use, especially when they were found within waterways (Ferguson 1992; Ogata 1995). The presence of these marks on contemporary Ghananian vessels added support to the notion of an American connection to an Old World popular tradition (Ferguson 1992: 10; Gundaker 2011: 178–180). Others argue that the "X" symbols represent maker's marks (Joseph 2007: 2, 7).

Colonoware Use

The use of colonoware has traditionally diverged into two primary, but not necessarily mutually exclusive, paradigms. One approach claims that its use was associated with specific ethnic groups. The other explanatory scheme suggested that a status of bonded labor was a better predictor of the presence of colonoware at any given site. Noël Hume's (1962: 5, 12) initial identification and

assessment of Colono-Indian ware argued that, at least in the Virginia Tidewater, the ware was produced by the Pamunkey Indians for use by enslaved labor, beginning late in the seventeenth century.

Decades of archaeological investigations revealed that there were regional differences in the proportion and amount of colonoware recovered at any given site. Influenced by data recovered from the archaeology of large plantations, preliminary investigations suggested that colonoware was reliably employed in situations characterized by large populations of enslaved laborers who lived some distance from the planter's home. It was argued that the isolation of such diasporic African communities fostered the retention of Old World traditions as well as the development of new material expressions of African American praxis.

Recent archaeological investigations conducted at sites characterized by small populations of enslaved workers, including middling plantations and small farmsteads, have also recovered colonoware, though in smaller proportions of their associated ceramic assemblage. In the Upper South in general, colonoware typically formed a small portion of those ceramic assemblages of which it is a part. Noël Hume (1962: 5) found that no more than 5% of the domestic assemblages which he studied were comprised of colonoware (See also Galke 2009: 306–307). In contrast, work in South Carolina during the 1970s demonstrated that colonoware vastly outnumbered European- and Asian-derived ceramics on some colonial sites (Ferguson 1992: 7–10, 36–37).

While broad conclusions over space and time are not warranted, a persistent association between laborers and coarse earthenwares of brown, red, or orange paste – such as colonoware – has been noted in a number of Chesapeake regional studies. Beginning in the eighteenth century, a culture developed that increasingly associated "whiteness" with order, freedom, refinement, power, and privilege (Andrews and Fenton 2001: 123–131; Heneghan 2003: 130–131, 133; Loren 2000; Yentsch 1991: 214–219). Coarse earthenwares and red-pasted ceramic objects were relegated to lower classes and to the enslaved.

This pattern of coarse, earth-toned ceramics associated with lower-status and lower-class people has been documented both in smoking pipe forms (Henry 1979: 32–33; Galke 2009: 305, 310, 311, 312, 313, 20–321; Monroe and Mallios 2004: 70, 80) and for vessels throughout the colonial and antebellum periods especially in British North America (Yentsch 1991). Additional studies that explore variables in economics, environmental conditions, ethnicity, class, status, and other cultural influences are needed. Scholars must always bear in mind that conclusions are likely to be most confidently applied locally or regionally, but not globally.

Conclusion

Colonoware represents a hybridization of cultures representing the interaction of Indigenous Americans with Old World migrants in the New World. Avenues of research include the degree to which colonoware use was influenced by food ways, ethnic expression, medicinal preparation, gender, economic status, or the sale of materials for which the colonoware vessels merely served as a containers. Though colonoware is still made and used in parts of the Caribbean today, in North America it appears that the use of this ware dropped sharply at the turn of the nineteenth century. In this era of mass-produced, readily available, and inexpensive household ceramics, it seems that there was a little need for an inexpensive, locally made pottery. Colonoware provides material culture specialists a dynamic, multivocal artifact that reflects a local, community-level moment of hybridity and transformation in any given culture.

Discerning who used this ware within these respective, and often multiethnic, contexts requires conscientious study along dimensions of class, status, and ethnicity. Colonoware has been recovered from homes occupied by enslaved laborers, Indigenous Americans, and even – in some rare contexts – upon the tables of the elite. Some material culture analysts suggest that colonoware represented an ethnic marker, reflecting consumers of African descent who used the ware in deliberate resistance to

mainstream consumer taste. Others suggest that labor class determined the use of colonoware at the household level. The hybridity of this ware reflects local constraints and opportunities. Efforts to dissemble the inspiration for its creation, use, and attributes present both challenges and opportunities for rich interpretations of past social, economic, and political environments. Any effort to comprehensively understand colonoware – or, more broadly, ethnicity, class, and identity in general – must consider the rich archaeological data that have been generated at sites of other major colonial powers: British colonial, Spanish colonial, and French colonial sites. Comparing the chronological appearance, use, distribution, attributes, and form between different colonies reveals how different approaches to colonization influenced material culture.

Colonoware encapsulates the hybridity of early international contact, reflecting the shared histories of Indigenous Americans, Africans, Europeans, and Asians. Multiple dimensions of identity and culture were preserved in this ware, but discerning those intricate relationships from any given sherd or vessel defies simplistic explanations. The complex sociocultural interactions of the contact era, and the conditions under which colonoware was created, consumed, and distributed, foster engaging analysis, but broad generalizations will always remain impractical.

Ceramics: Conservation and Preservation

Nancy Odegaard
Arizona State Museum, Department of Materials Science and Engineering, School of Anthropology, University of Arizona, Tucson, AZ, USA

Introduction

The study of ceramic manufacture, embellishment, trade, and permanence is only possible if examples are preserved. Ceramics are perhaps the first synthetic materials made by people, and they continue to contribute much to the study of human culture. By uniting earth, water, air, and fire, a type of artificial stone is created that can endure thousands of years. While often considered indestructible, ceramics include a wide range of physical properties that can also make them fragile and fragmentary. An ever-increasing use of analytical technology to derive chemical and physical details has required the conservation and preservation of ceramics to move well beyond mere washing and reassembly of sherds.

Definition

The word ceramic is from the Greek word *keramikos*. Ceramic objects include pottery which is a broad term referring to wares or vessels made from lower fired clays. Pottery types may include utilitarian or decorative vessels, tiles, sculpture, and figures. Damage may be the result of fire, frost, impact, plant roots, soluble salts, thermal shock, water, and human use.

Conservation is the profession devoted to the preservation and protection of cultural property for the future. Activities include examination, documentation, treatment, and preventive care.

Key Issues/Current Debates/Future Directions/Examples

Natural clays are formed by long-term mechanical weathering of rocks and are found at the earth's surface throughout the world. The varying mineral composition of clays produces a range of desired properties or visual effects when fired to form ceramics. Archaeological ceramics are commonly made from iron-rich clay that becomes red or black ceramic after firing at a relatively low temperature (below 900 °C or 1650 °F). A slip or thin layer of dilute clay material applied to the surface may create a different surface color and texture. Less common in archaeological examples, but important, is the use of a glaze which is a glossy thin glass-like layer fired onto the ceramic surface. Many artisans experimented with available materials and techniques to create different finishes, designs, or colors. While the range of ceramic types is wide, it is the lower-fired ceramics that deteriorate more readily through mechanical and chemical degradation (Buys and Oakley 1993).

Lower-fired ceramics, sometimes identified as terracotta or earthenware pottery, tend to be porous and will absorb water easily. This makes them more sensitive to deformation, erosion, and salt damage. Exposure to water may be from the ground or deposition location, use as a storage container/cooking pot, or high humidity.

Highly alkaline or acidic conditions are damaging to ceramics through chemical deterioration. Acids are known to attack glazes or calcareous fillers in the clay body. Alkaline conditions more often affect glazes through breakdown of the silica component, resulting in iridescence or surface exfoliation.

Salts that are dissolved in water enter porous pottery and crystallize when dry. Recrystallization may become a cyclic process, and because the reformed crystals can continue to grow in size they occupy more space, and they force the pottery to break up or flake. Different soluble salts such as carbonates, sulfates, nitrates, and chlorides have different properties and mechanisms.

If used as cooking vessels, serving bowls, or water jars, ceramic surfaces are more easily abraded, cracked, and damaged by repeated charring, residue depositions, and the mechanical action of ladles and stirrers. Pottery objects that are softened through burial moisture may have plant root damage especially if there is nutrient-rich material inside. If humidity is high, mold and bacteria growth may be problem.

When ceramics are heated beyond their original firing temperature, they are likely to distort and melt. If there are glazes, these may become fluid and change color. Also, existing cracks may become sprung. Dating ceramics under these conditions is compromised. Conversely, when ceramics are exposed to long periods of very low temperatures, ice may form in the pores and cause spalling due to mechanical pressure.

The main hazard to ceramic objects is poor handling. Their brittle nature causes them to break, crack, and chip if they are dropped and suffer an impact. However, durable a ceramic may appear, it should be considered fragile. Ceramics often have weak joins between the handles and body. Never lift a ceramic by the handle, knob, or rim. Always check the weight and balance before you lift a ceramic object. It is important to use both hands and support ceramic pieces from the base when lifting. Use clean hands to avoid fingerprints on the surface and wear nonslip gloves with glazed wares to prevent accidents during handling.

Years ago, full restoration was the norm because the study of archaeological ceramics was limited to shape, style, volume, technique of production, and decoration. As the methods for chemical and physical analysis improved, ceramics came to be studied as evidence of human behavior and technological achievement as well. The earlier criteria for conservation offered techniques for full cleaning with acids and detergents and restoration techniques involving adhesives, splints, fills, and the inpainting of missing designs (Plenderleith and Werner 1971). Modern trends involve thorough consideration of cleaning (to avoid loss of residues, coatings, and temper) and the use of reversible adhesives for assembly of only original and vessel-specific sherds and parts. The conservation of archaeological ceramic items seeks to preserve all evidence that may yield insights to the date and temperature of the kiln fire, the temper, and any residues that illustrate aspects of function and use. Future researchers need to know if they are working with original or modified ceramics (Tennent 1999).

Routine cleaning presents risks. If residues are to be studied, a soft brush may be used (one hand holds the brush and the other steadies the object). Brushes should not be used to scrub or agitate the surface with friction, and care should be taken around painted, decorated, or damaged areas. Wet cleaning is typically necessary for initial sorting, but the water should be tested for pH (close to neutral) and soluble salts (low) prior to use. Pottery that is unevenly fired or simply baked will dissolve. Wet objects should be kept damp until they can be fully examined in a laboratory. Acid cleaning typically causes irreversible damage and should be carefully considered based on

specific goals and protocols based on tested procedures. Professional conservators may use water and chemicals to clean but will take great care to test all surfaces, use purified water, and provide for even drying to avoid the development of unsightly tide lines or other surface deposits. Detergents and soaps are never recommended for most archaeological pottery.

Pieces that have been previously mended or restored often become weak or fail completely as the adhesive ages. A wide range of mending materials and techniques have been tried through the ages. In fact, ancient mends, including drill holes to hold breaks together with ties and natural adhesives such as pine resins, animal glues, bitumen, or lac, are important evidences to preserve. The mending, stabilization, or restoration of valuable ceramics is not appropriate for amateurs. It is easy to damage and misalign the edges of sherds, to select and apply an inappropriate adhesive, and to create an unstable or misleading object. Conservators have the skills and knowledge to carefully select modern (easily distinguished from original) materials to best match the ceramic material and its technology while considering the type of damage present (Acton and Smith 2003). Knowledge of the ceramic traditions, the chemistry of materials, and practiced dexterity enable conservators to execute successful treatments. Also, conservators always include documentation with their treatments.

Closed display cabinets provide the best protection from dust, lint, insects, and vibration. Use care to provide adequate space between pieces so that they do not touch each other and avoid stacking. Metal spring-type plate hangers should not be used on the majority of archaeological ceramics as these are designed for high-fired porcelain or stoneware ceramics. The exaggerated stress of the spring may open and extend cracks or chip fragile edges. If a piece is cracked, do not lean it to support its own weight.

The preservation of archaeological ceramics has a long tradition that is linked to the very long history of archaeology, but the origins of professional conservation may be more closely linked to the mid-twentieth century. The guiding principles for any conservation action are reversibility and documentation.

Ceramics: European Cream to Whitewares in the USA

Teresita Majewski
Statistical Research, Inc., Tucson, AZ, USA

Introduction and Definition

A growing market demand for white-bodied wares led to the development of "creamware" in Britain in the 1740s. The Staffordshire ceramic industry had been transformed during the 1720s–1740s, with changes in scale, organization, and manufacturing methods that set the tone for pottery production elsewhere in Britain and beyond. The production of white-bodied earthenwares in tableware, teaware, tiles, and decorative forms in Staffordshire required white-firing clays from Devon and Dorset and flint used in clay bodies and lead glazes from the south and east coasts of England (Barker and Majewski 2006: 214). Josiah Wedgwood has often been credited with the invention of creamware, but it is now evident that he was one of a number of Staffordshire ceramic producers also making the ware (e.g., William Greatbatch and Josiah Spode).

Creamware was often undecorated or minimally embellished through molded detail and simple enameled or painted decoration but also was made in various rococo and neoclassical styles using elaborate molding, colored glazes, over- and underglaze enameled and painted decoration, and various forms of printing as well as engine turning. By the early 1760s, creamware and other Staffordshire ceramic products were being exported in vast quantities to the British colonies in America and the West Indies as well as to almost every port in Europe (Barker 2001: 81).

Creamware was produced into the nineteenth century, but pearlware became the earthenware body of the early nineteenth century, and it was nearly always decorated. The ware was introduced by the mid-1770s and appears in archaeological contexts in America soon thereafter. Early on, decoration was a blue-tinted glaze over a white body with underglaze blue Chinese-style painted decoration in imitation of Chinese porcelain. Molded and painted "shell-edge" was used on less-expensive tablewares, and painted floral decoration was common on table- and teawares. By c. 1800, higher-end tea- and tablewares were transfer printed. In the 1780s, transfer printing using images transferred from engraved copper plates was introduced to earthenware manufacture and allowed for mass production of identically decorated wares. Printed wares were initially mainly in blue but from the late 1820s appeared in a range of colors, and color and style of print are useful for dating purposes. Although creamware manufacturers rarely marked their wares (except for some exceptions, such as Wedgwood and some of his contemporaries), with pearlwares, the practice became increasingly common, particularly on printed wares. Makers' marks can contain a wealth of useful information, including identity of manufacturer (which can be linked to company histories and dates) and occasionally the importer.

While archaeologists define white-bodied earthenwares as creamware, pearlware, or from c. 1830 as "whiteware," nineteenth-century manufacturers defined and marketed their products by type of decoration, e.g., printed, painted, dipped, and edged. The popularity of decorated ceramics, particularly transfer-printed earthenwares, increased throughout the nineteenth century, greatly changing the composition of excavated ceramic deposits and allowing for more interpretive analysis using the cost of wares (known from documentary evidence) to construct socioeconomic profiles of ceramic users, following George Miller's seminal work.

Beginning in the 1850s, the popularity of transfer-printed wares declined in the Americas, although a resurgence occurred in the last quarter of the nineteenth century that lasted until early in the twentieth century. Creamware, pearlware, and whiteware are all nonvitreous, white-bodied earthenwares, but by the mid-nineteenth century, the British were producing and exporting large quantities of molded "ironstone china" or "white granite," a heavy-duty semivitreous, white-bodied earthenware not to be confused with either the patent ironstone wares of the earlier nineteenth century or with porcelain and bone china of any period. White granite wares were durable, withstood shipment to the frontier regions of North America, and emulated the then-stylish and expensive French porcelains that were being exported to America (Barker and Majewski 2006: 216).

Key Issues/Current Debates/Future Directions/Examples

The sheer quantities of British white-bodied earthenwares recovered from excavations at Staffordshire factories known for their export business as well as from archaeological contexts in the USA and in the Americas undoubtedly attest to the British ceramic industry's superior capabilities for mass production of "useful" wares that could be effectively transported and distributed to American markets at a reasonable cost to the consumer. During the period beginning in the late eighteenth century and continuing almost to the end of the nineteenth, these markets included the Caribbean, South America, Central America, Mexico, Canada, Alaska, and everywhere in what was to become the continental USA. Among the consumers of British-made ceramics were urban

dwellers purchasing from local shops; rural populations being supplied by country stores and traveling salesmen; early settlers, miners, ranchers, and the military on the frontier; and Native Americans. Sophisticated trading relationships have been documented between importers in major American cities and manufacturers in Britain. Trading companies also played a role in the ceramic export-import process. For example, in the mid-1830s, the Spode/Copeland pottery of Staffordshire became the supplier of tableware and toiletware to the Hudson's Bay Company, continuing in this capacity until the 1850s in the USA and until the early twentieth century in Canada.

The American ceramic industry for many years could not compete with British-manufactured white-bodied wares, even though American-produced (and American-consumed) redwares, yellowwares, and stonewares had a long and successful history. Many Staffordshire potters immigrated to America, bringing their knowledge and experience with them. By later in the nineteenth century, American potteries in the clay-rich Ohio Valley and the Northeast were gainfully making nonvitreous whitewares as well as white granite wares, with the latter laying the foundation for the successful American hotelware industry. Ceramic assemblages dating to the turn of the twentieth century and after come to be dominated by American-made ceramics. Trade tariffs, changing consumer profiles, and increasingly reliable and more cost-effective transportation made it possible for other pottery- and porcelain-producing countries to gain a foothold in the American market, although British white-bodied earthenwares continued to be exported to the USA in lesser quantities after 1900.

This discussion of European creamwares to whitewares in the USA has emphasized the British (particularly Staffordshire) ceramic industry, rather than that of Continental Europe. This is because British products are the ones that appear most frequently in American archaeological contexts and because unfortunately less is known about the white-bodied earthenwares produced on the continent and whether they were exported in quantity to other markets (or primarily manufactured for home markets), although work is beginning in this area. Interestingly, the majority of Staffordshire ceramic exports went to European destinations until 1835, after which date the USA became the primary market (Barker 2001: 81).

Despite variable global economic and political factors, the Staffordshire potters succeeded in the international market because their products appealed to the mass-consuming lower, lower-middle, and middle sectors of the market who were interested as much in the price of their ceramics as they were in quality. Ewins (1997) charts the development of the Staffordshire trade with North America, demonstrating how the potters gained access to the American market and how they were able to respond rapidly to changing American tastes.

Barker and Majewski (2006: 215) note that "The success of Staffordshire ceramics during the later eighteenth century led to the establishment of factories making Staffordshire-type wares in many parts of Britain, in [Continental] Europe. . ., and in North America. . . ." Standardized production developed not only because potters were moving to other areas but because the Staffordshire-based infrastructure supplied everything other producers would need to make white-bodied wares. To date, most scholars of continental ceramics have either focused on earlier time periods or on high-end ceramics such as the hard-paste porcelains produced by factories benefitting from royal patronage (e.g., Meissen in Germany or Sèvres in France). Some significant exceptions include documentation of the British-type whitewares made by Petrus Regout of Maastricht in the Netherlands that were produced for European and overseas markets for much of the nineteenth and twentieth centuries, of British-made creamware (in Canada), of British and French white-bodied earthenwares exported to the French West Indies, and of the *faiences fines* industry in France. Unfortunately, more foundational and synthetic work on ceramic bodies and forms using documentary and archaeological evidence remains to be done on the European white-bodied-earthenware industry before historical archaeologists will be able to accurately identify

and fully assess the contribution of other ceramic-exporting countries to the ceramics found in the archaeological record in the USA.

Ceramics: Majolica in Colonial Latin America

Tony Pasinski[1] and Patricia Fournier[2]
[1]Independent Investigator, La Antigua Guatemala, Guatemala
[2]Posgrado en Arqueología, Escuela Nacional de Antropología e Historia, México, DF, Mexico

Introduction

Majolica, often called tin-glazed earthenware today, can be found in colonial archaeological sites stretching from Canada to Argentina. During the sixteenth century, production acquired significant importance in Europe where it was known as *maiolica* in Italy, *faience* in France, *faiança* in Portugal, *Delft* in the Netherlands, *Delftware* in England, and *loza blanca* in the Spanish Empire. It was exported from those countries to the New World where, eventually, in a number of colonies it was replaced by local production.

Definition

In Latin American colonial sites, the study of excavated European and locally made majolicas, such as tableware and utilitarian vessels, decorative and architectural elements, can lead to an understanding of internal and external trade patterns, the level of reliance on contraband trade, and the degree of local consumerism.

Key Issues

The progressive Spanish conquest of the New World in the sixteenth century held great potential for Old World ceramics merchants – that of supplying the needs of settlers and government officials with simple majolica tableware, popular with those who could afford it, and for the more expensive, ever-changing, highly decorative Iberian and Italian majolicas popular with the elite. Spanish archival records from that time show that both were exported with each sailing of the fleet to New Spain/Honduras and to Panama. Archaeological evidence confirms their presence in varying degrees in almost all Spanish settlements that date to that period.

However, archival records originating in the interior of mainland colonies such as Guatemala indicate early complaints about the high cost of imported goods and later complaints about the irregular to almost nonexistent schedule of fleet sailings to their ports. With no Crown prohibitions against the local manufacture of ceramics, a lower-cost majolica production began on the New World mainland in the 1550s in Mexico City and gradually spread to Puebla de los Angeles, Oaxaca, Santiago de Guatemala, Panama la Vieja, and Cuzco well before the 1600s (e.g., Goggin 1968; Deagan 1987; Lister and Lister 1987; Jamieson 2001). The archaeological evidence from the first four sites tends to indicate that as local production quantity and quality increased, the amount of imported Iberian and Italian majolicas decreased, to the point that by the mid-seventeenth century, there is little to no evidence of them. This contrasts sharply with Brazil, Uruguay, and Argentina, for example, where there were no local industries and where the majority of archaeological majolicas are European.

Majolica made in Mexico City and Puebla has been found in archaeological deposits in New Spain, the northern frontier towns and mission settlements stretching from present-day California to Florida and into the Carolinas, the Kingdom of Guatemala, Cuba, and to lesser degrees in a number of southern colonial Latin American sites. Majolica from Panama reached at least as far north as Guatemala and as far south as Argentina and Chile. Fragments of vessels produced in Oaxaca and Santiago de Guatemala, however, are seldom found outside of the area of their immediate control, sphere of influence, or local trade routes (Figs. 1 and 2).

Ceramics: Majolica in Colonial Latin America, Fig. 1 Mexican majolica. Puebla Polychrome, soup plate c. 1650–1725

Ceramics: Majolica in Colonial Latin America, Fig. 2 Guatemalan majolica. Chacra Tetrachrome, wash basin c. 1750

The widespread distribution of majolica from Mexico City and Puebla in the northern part of the Spanish New World was a direct result of supplying the vast area under the control of the Viceroyalty of New Spain and the lack of restrictions on trade with Guatemala. With the exception of Cuba, prohibitions on commerce between colonies in different administrative areas severely limited the possibility of a much broader and more significant geographic distribution.

Panama was at the hub of the trade route between Spain and the Viceroyalty of Peru, and at the hub of trade, prohibited or not, between the Pacific ports of present-day Mexico, Guatemala, El Salvador, Nicaragua, Ecuador, and Peru. During the time in which it functioned, the majolica industry in Panama was a major supplier of fine majolica to the southern Viceroyalty, but no more than a minor player in northern areas along the Pacific coast competing with the workshops of New Spain. The Panama industry came to an abrupt end following the destruction of Panama la Vieja by pirates in 1671.

Majolica industries in early centers such as Oaxaca, Santiago de Guatemala, Cuzco and in later centers such as Lima, Quito, Cuenca, Cartagena de Indias, and Popoyán played an important role in providing vessels for the table and for decoration that, in spite of differences in quality between them and "foreign" counterparts, appear to have suited the tastes of the local population at prices that were more affordable in their respective areas than imports. The added cost of transporting low-grade majolica over great distances may account for the lack of a broader distribution of these products. An exception was the majolica industry founded in Guanajuato in the late 1700s; it supplied consumers in the greater part of northwestern Mexico.

Majolica from Portugal is seldom found in the towns of the Caribbean Basin and Pacific coast, but is present in Brazil, Uruguay, and Argentina (Fig. 3). French and Dutch examples related to open and contraband trade can appear in archaeological deposits of the Caribbean and surrounding mainland, and the southern Atlantic coast. British majolica has been reported in Argentina.

To date, the published evidence of majolicas in colonial Latin American tends to show that there were people or groups that could afford fine-grade majolica from Europe and from other administrative areas of the New World, and that the founding of a local industry could obviate the need for imports in meaningful quantities. Thus, archaeological deposits can present significant differences from colony to colony and from site to site within

Ceramics: Majolica in Colonial Latin America, Fig. 3 Portuguese faience. Polychrome plate, mid-eighteenth century

a colony, which need to be understood by referencing archival data and by interpreting the evidence in the framework of social theories and historical issues. In addition, majolica provides a valuable tool for dating colonial sites based on the development of thorough typological schemes, especially in the case of European, Mexican, and Panamanian examples, and in all cases for recording the tastes, customs, and diet of the local population.

Future Directions

Ongoing research to determine the provenience of specific types supported by compositional chemical studies, for example, instrumental neutron activation analyzes, has been key to understanding where the vessels represented in archaeological collections were produced and thus to infer changes in trade and consumption trends through time (e.g., Fournier et al. 2009).

Refined typologies are still required for Guatemala and for several South American areas. In many regions, there are scant archaeological studies and in some cases, traditions recorded in documentary sources have not been studied in detail. In addition, few studies have been made of the historical records of prices to compare market costs of different ceramics and to gain a better understanding of consumerism in colonial Latin America.

Ceramics: Roman Republican and Early Principate

Laura Banducci
The Archaeology Centre, University of Toronto, Toronto, ON, Canada

Introduction

Roman ceramics served domestic and commercial purposes; they appear as lamps and perfume containers, as well as vessels for the preparation, cooking, service, storage, and transportation of foodstuffs. In archaeological sites in the Roman world, pottery is the most frequently found material. It is found in burials and ritual foundation deposits; fragments were frequently used to level floors for construction, to fill in negative features such as drains and cisterns, and reused whole, and in part, as part of wall construction material.

This entry covers material produced in Italy and the Roman provinces around the Mediterranean

from about 500 BCE until the late first century BCE. In this period the definition of what it meant to be "Roman" was in its early stages of development. In the fifth and fourth centuries BCE, the city of Rome was only beginning to expand its reach outside the city limits, and the multiple entities of the Italian peninsula interacted with it and each other in constantly changing ways. By the end of the third century, Rome controlled the Italian peninsula, by the end of the second century, the whole of Greece and western Asia Minor, and by the end of the first century, Egypt and the Levant. As a result of this continued expansion, this entry covers material produced in various areas of the

Ceramics: Roman Republican and Early Principate, Fig. 1 Roman kilns of circular design. (Cuomo di Caprio 2007: Fig. 168).

Ceramics: Roman Republican and Early Principate, Fig. 2 Roman kilns of rectangular design. (Cuomo di Caprio 2007: Fig. 169)

Mediterranean when they were under Roman control – reflecting the ever-expanding empire. The material discussed here is frequently found on archaeological sites in Italy and the wider Mediterranean together with material exported from outside areas of Roman control – together with ceramic and metal vessels which were Greek-made, Etruscan-made, or from the Near East or Egypt. The multitude of influences and interaction and the increasingly dynamic and mobile Roman world of artisans and consumers mean that ceramics which are "Roman" are difficult to discuss in a cultural vacuum.

Definition

Production

The majority of pottery in the Roman Republican period was made on a fast wheel or in a mold which was probably mounted on a wheel. The exceptions to this are *dolia*, large storage vessels which would have been made by coiling or hand building. Roman wheels were probably flywheels, or kick wheels, and usually made of wood; very few stone examples survive. Vessels were stacked in updraught kilns of quadrangular or circular design and fired at varying temperatures depending on the clay type and the desired effect. Typically, however, firing temperature for Roman pottery is between 850 °C and 1000 °C (Cuomo di Caprio 2007: 497, 508–17).

This wheel-made pottery was produced in workshops throughout Italy and the Roman Mediterranean. Simultaneously, however, there was likely a small-scale handmade pottery industry in areas throughout the Mediterranean which also engaged in active trading (Peacock 1982: 75–113) (Figs. 1 and 2).

Common Roman Ceramic Types of the Republic

Roman ceramic typologies have been created based on a combination of different attributes which have developed haphazardly over the centuries as groupings of artifacts have been recognized. The attributes governing the identification and naming of different ceramic types are not standardized. Some ceramic types are distinguished by a combination of their clay fabric composition, their form, and their surface treatment; some mainly by their fabric and surface treatment; or some mainly by their understood function.

Black Gloss

Produced: 400 BCE to 50 BCE.

Location of Production: Black gloss vessels were produced in workshops throughout Italy. Early in the study of black gloss, scholars hypothesized main production centers near the Bay of Naples (called Campana A production), in southern Etruria in what is now northern Lazio, and southern Tuscany (originally called Campana B), and in Sicily (originally called Campana C) (Lamboglia 1952). Scholars have now acknowledged the role of smaller-scale local workshops in towns throughout the Italian peninsula which became especially active in the later history of the ware's production. There were workshops in Taranto, Cales, Volterra, Tarquinia, Falerii Veteres, Cosa, and Aleria, to name but a few (Cibecchini and Principal 2004: 159).

Identification: This pottery is also called *vernice nera* or black glaze; however, modern English-language publications increasingly refer to it as "black gloss" in recognition of its surface sheen being due not to glaze, but to a fine layer of slip made with the same clay as the ceramic body. The vessel would have been made on a wheel, then typically left to dry until it was leather hard. Then the vessel was either immersed in a bucket of slip or, particularly in higher quality examples, painted with slip.

Black gloss vessels were finished by firing them in a kiln between 900 and 1000 °C sintering the slip to create its solid sheen (Mirti and Davit 2001: 21; Cuomo di Caprio 2007: 295, 314–7). Their external black color is achieved by firing the vessels in a reducing, or oxygen-poor, atmosphere. Ancient consumers desired vessels with this black sheen probably because it was a less-expensive way to have vessels which looked like bronze and silver.

The production of these vessels began as an imitation of vessels made in Attica, in Greece. The

earliest examples from Italy emulate the Greek pieces in their red-orange matrix and their thickly applied iridescent surface slip. Throughout the fourth century BCE, workshops in southern Italy produced variations of this type with varying levels of quality (Stanco 2009a: 21).

The fourth century is also when black gloss painted over with linear and foliage designs was produced in southern Etruria and probably also east in Faliscan territory. This ware, often referred to as "overpainted ware" or "*sovradipinta*," is found in Greek-inspired shapes like *skyphos* cups and jugs with cutout necks. Vessels were covered in black gloss and then painted with fine lines of clay-based paint in white, pale yellow, orange, brown, or pink (Pianu 1982).

In the late fourth century BCE, a particular variant of black gloss vessels began being produced at workshops in the countryside around Rome in what is now northern Lazio and southern Tuscany and later also in southern Italy. This class of pottery is referred to by modern scholars as "*petites estampilles*" or "*piccoli stampigli*" because of the "small stamps" decorating the vessels' interiors. Vessels with these stamps appear in a handful of limited forms – typically, they are all variations of a small bowl with a defined ring foot (Stanco 2009a: 22). The stamps, about half a centimeter in diameter and most often palmettes and rosettes, are distributed around the central interior of the bowl. At the beginning of their manufacture, the stamps appear in fours or fives and are typically symmetrically arranged. Over the course of the development of the style into the late third century BCE, multiple stamps are gradually replaced by a single, larger central stamp (up to 2 cm in width) surrounded by incised concentric rings or rouletting (Stanco 2009b: 158 and Fig. 6a).

Ceramics: Roman Republican and Early Principate, Fig. 3 Jug with overpainted decoration. (Pianu 1982, pl. XXIX, n. 47c). (Courtesy of the Soprintendenza per i Beni Archeologici dell'Etruria Meridionale)

The third century BCE saw an expansion of the black gloss repertoire with the introduction of many closed-form pouring vessels in addition to bowls of various scales. Workshops at the cities of Volterra and Arezzo produced vessels with added clay décor on their exterior with forms very reminiscent of embossed metal vessels. Demand for Volterran production seems to have been widespread in the Po river valley (Stanco 2009a: 26–31).

By the middle of the second century, the shape repertoire of black gloss had changed significantly. The forms of what were once curved vessels with rounded edges became increasingly toreutic or reminiscent of metal (Morel 1981: 524–8; Cibecchini and Principal 2004). The open form shapes are more angular and have sharper rims and carination. Flat platters are increasingly common. These are the forms that become part of later Roman red gloss pottery such as *terra sigillata*. Stamps often appear decorating the central interior of the vessels; however, these are more rectilinear with palmette leaves appearing more angular and an increased use of rectangular stamps (Stanco 2009a: 32–3) (Figs. 3 and 4).

Eastern Sigillata

(Eastern Sigillata A, Cypriot Sigillata, Eastern Sigillata B, Çandarli Ware)

Produced: 150 BCE to 300 CE.

Location of Production: Various styles of what has generally been termed "eastern sigillata" were produced in particular locations throughout the eastern Mediterranean. In the Roman Republican period, the major producer of eastern sigillata A was probably located in what is now modern Syria (Lund 2005: 237).

Identification: The earliest type of this ware, and the one which appeared in the Republican period, has been termed eastern sigillata A (ESA). The interior clay matrix varies from yellow to orange and can be of a granular or smooth powdery consistency. It is very well levigated with few to no inclusions visible to the naked eye. Given how highly standardized the forms of ESA are, scholars have posited that it was made with the aid of molds (Hayes 1997: 20–1; Lund 2005: 238).

The slip, in contrast, is red-orange to red-brown in color. It was thickly applied by dipping the leather-hard vessel in slip before it was fired. This resulted in many extant vessels having a "double dipping streak" where the slip overlaps because one side of the vessel was dipped, the vessel was turned, and then the other side of the vessel was dipped (Hayes 1985: 9).

The earliest forms of ESA were several types of deep plates with both incurved or flaring rims and small bowls. Around the last quarter of the second century BCE, several new plate and bowl forms were added to this repertoire along with large krater (a large bowl for mixing water and wine) and jug forms (Lund 2005: 234).

A very similar red slipped ware, termed Cypriot sigillata, began to be produced in the early first century BCE. Cypriot sigillata was produced in western Cyprus, and the distribution of archaeological finds of this ware suggests that the island of Cyprus was its main market, with the West Coast of Turkey and Israel being secondary areas of consumption. Despite this rival production, ESA remained the dominant fine ware in the eastern Mediterranean in the first century BCE (Malfitana 2002: 155). Cypriot sigillata had very similar forms to ESA, but its different area of origin means that it has a different quality clay. Its clay matrix is more commonly brick red to purple brown in color with sometimes visible calcium inclusions. It too was dipped in slip and can have a "double dipping streak," but its slip tends to be applied more thinly and can be quite glossy and metallic (Hayes 1985: 79–80).

Gradually, the production of the other eastern sigillata wares and the introduction of red slipped fine ware produced in Italy, *terra sigillata*, took over the market in the east (Malfitana 2002, Fig. 3).

Italo-Megarian Bowls

Produced: Early second century BCE to end of first century BCE.

Location of Production: Central and/or Northern Italy.

Identification: These are hemispherical bowls or cups of around 13 cm in diameter which have intricate relief decoration on their exterior which most often appears in the form of foliage but can also include bands of meander, wave patterns, and sometimes faces. The vessels are made by placing a lump of clay in a mold on a wheel. They have a pale red-brown or grey fabric and are unslipped. No chemical or petrographic analysis has yet been done to associate specific clays or fine inclusions with production locations (Figs. 5 and 6).

Many of the cups have molded inscriptions naming their potters or workshop owners, and their study has therefore been focused on both establishing a chronology of their relief decoration and on attributing unstamped vessels to known artisans. The Italian version of this vessel appeared a few decades after they started to be made in the Greek East in the late third century BCE. The Greek examples are distinguished from

the Italian ones because they bear a metallic-colored slip, have less sharply concaved rims, and are not so strictly hemispherical (Rotroff 1996: 316). The design and decoration of both the Italian and the Greek productions seem to owe a lot to the design of metal vessels from the same period (Marabini Moevs 1980: 185).

Thin-Wall Pottery

Produced: 200 BCE to CE 300.

Production Location: In central and northern Italy, probably in the Po Valley, at Aquileia, and near Ravenna.

Identification: These are small cup or bowl forms which have walls as thin as 0.5 mm. They often have two handles. Their clay is well levigated and usually red-brown to grey-yellow. Sometimes they have a thin black-brown or red-brown slip which had been applied with a brush, but this is not a consistent feature. Often their exterior is left without further ornament, but it is also common to have rouletting or barbotine (added bits of clay) patterned around their central exterior. In general, in the Republican period thin-walled vessels are usually plain or have barbotine design, and then the applied decoration gets progressively more complex and more formal (leaves, crescents, animals) into the first century CE.

These vessels, like many fine ware forms in the period, are often explained as deriving from or referring to metal prototypes (Marabini Moevs 1973: 36). The repertoire of forms in the Republican period is very varied, and scholars have generally interpreted their forms as deriving from two cultural predecessors: the Golasecca civilization, or more generally Iron Age peoples of north Italy, and the Hellenistic world, namely, the Greek East (Marabini Moevs 1973: 36–8; Gervasini 2005: 285). Forms stemming from Iron Age Italy are taller than they are wide and have a slightly more restricted opening and no slip, whereas forms which are similar to Hellenistic shapes are low, wide cups with handles molded like metal (Figs. 7, 8 and 9).

Common Ware

Produced: 700 BCE to today.

Location: Throughout the Mediterranean.

Identification: Termed *Ceramica comune* in Italian, common ware is a vast ceramic category including vessels meant for the preparation, serving, small-scale storage, and cooking of food. There is a great deal of inconsistency in the scholarly literature regarding this category of material; some scholars suggest that it is a category where material that does not fit in any other category is placed, while others see the unifying theme of "common ware" as being the daily preparation of food and a focus on function over aesthetic. This category is also referred to as "utilitarian ware" and as "coarse ware" in English-language publications and in reference to material which was produced in the late archaic period.

It is useful to subdivide this category in two ways: there are vessels used for cooking (in Italian, *ceramica comune da fuoco*, "for the fire") and those used for preparation, serving, and storage (*per la preparazione, da mensa, da dispensa*). These vessels have fundamentally different clay characteristics and forms. Most generally, cooking vessels in the Roman world are made with noncalcareous clays and are coarse-bodied, that is, they have a tendency to have more temper (either naturally occurring in the clay or added by the potter). These technological choices make them resistant to thermal shock. Roman cooking wares in the Republican period generally have an open form for easy access to the food. They appear in both deep pots ideal to contain liquids and soft foods as well as low-walled flat pans for roasting and grilling vegetables and meats.

Vessels suited for the preparation, serving, and storage of food, conversely, need to be relatively resistant to mechanical shock, that is, damage due to bumping or knocking. They tend to be made with calcareous clays which have a much lower concentration of inclusions when compared to cooking wares. The most common preparation and serving vessels made in central Italy in the second and first centuries BCE were fired between 900 °C and 1000 °C in a reducing atmosphere and then cooled in an oxygen-rich atmosphere. The affect is that they are typically light beige to pink-yellow in color.

While the production of common ware is generally thought of as more locally oriented, it is increasingly clear that common wares both for cooking and for preparing and serving which were made in central Italy were exported around the Mediterranean beginning as early as the late

third century BCE and especially by the late first century BCE (Olcese 2003: 21–3) (Figs. 10, 11, 12, 13 ,14 and 15).

Transport Amphorae

Produced: From the third century BCE to end of first century BCE.

Location of Production: Italy and the West Mediterranean basin.

Identification: The shape of Roman amphorae, with their ovoid body, typically narrow neck and base (often ending in a point), and double handles comes out of a long tradition of similar storage and transport containers produced and circulated around the Mediterranean by Phoenicians and Greeks since the eight century BCE (Caravale and Toffoletti 1997: 52–89). Amphorae contained most often wine or olive oil but also fish sauce (*garum*) and possibly dry goods like wheat and nuts (Peacock and Williams 1986: 90). Scholars have determined the primary contents of different amphorae types from the painted labels on their exterior and from chemical analysis of residues from their interior.

Different amphora shapes can be attributed to the contents they were intended to hold, characteristics of the local clay, form precedents in their region of production, and transport concerns like how far they needed to be transported until they reached a harbor yard and the kind of ship in which they were to travel (Fig. 16).

Ceramics: Roman Republican and Early Principate, Fig. 15 Bowl for preparing food (*ciotola*). (Dyson 1976: Fig. 5, CF 66) (Courtesy of the American Academy in Rome)

There are several prominent amphora types in the Roman Republican period. *Greco-Italic* amphorae were produced in central Italy and the western Mediterranean from the third century BCE to the mid-second century BCE and are most obviously identified by the triangular profile of their rim. This triangle becomes progressively more elongated toward the end of their production date. The body of this amphora is ovoid, with a pointed base, a cylindrical neck, and two flat vertical handles. The typical height of a complete amphora is 80–90 cm (Caravale and Toffoletti 1997: 97). The fabric color varies, but in general it is buff-yellow to pink, and the exterior is slightly white. Greco-Italic amphorae held primarily wine.

Dressel 1 amphorae are similar to Greco-Italic in design features but have a narrower body and are generally more elongated. Dressel 1A and 1B also have quite a pronounced shoulder carination. Their overall height is 100–120 cm (Caravale and Toffoletti 1997: 98). Production of this type ran from the middle of the second century BCE to the late first century BCE in west-central Italy. These amphorae also began to be imitated by potters in southern France and Spain. Examples of Dressel 1 are found concentrated in Italy but also throughout the Mediterranean basin and in Britain. These vessels primarily transported wine, but perhaps also olive oil (Peacock and Williams 1986: 87, 90, 92).

http://archaeologydataservice.ac.uk/archives/view/amphora_ahrb_2005/details.cfm?id=324&CFID=5196568&CFTOKEN=46649964

Another wine-carrying amphora from this period comes from around the Adriatic coast (Caravale and Toffoletti 1997: 104; Sondi and Slovenec 2003: 252). Amphorae of Lamboglia 2 type are very similar in style to Greco-Italic amphorae but with a shorter base point. Overall, they are typically 80–95 cm in height. These amphorae were produced from the late second century to the late first century BCE and are found primarily in the eastern Mediterranean.

http://archaeologydataservice.ac.uk/archives/view/amphora_ahrb_2005/details.cfm?id=229&CFID=5196568&CFTOKEN=46649964

Finally, *Brindisi-type* amphorae from southern Italy are much more squat and wider than the

Ceramics: Roman Republican and Early Principate, Fig. 16 Schematic of how amphora are stacked inside the holds of ships. (Caravale and Toffoletti 1997: 40)

above examples and have handles which are round in section instead of flattened ovoid. They were produced from the late second to the mid-first century BCE and probably held olive oil (Peacock and Williams 1986: 83).

"Presigillata"

This was a term first coined by N. Lamboglia in 1951 to refer to what he interpreted as a transitional ware between black gloss pottery and pottery of similar manufacture which had a red slip. It has since come to be used to refer instead to any vessels with a red gloss which predate the manufacture of *terra sigillata* in the mid-first century BCE, and most problematically, it is often used when the ceramicist is unsure of the class or origin of the slipped material. It is generally agreed that because of the term's lack of precision, its continued use is problematic and unhelpful (Wells 1990).

Historical Background

The study of Roman ceramics, like many fields of classical archaeology, has its roots in art history. The methods of connoisseurship used in the study of Greek vase painting were similarly applied to the study of Roman fine wares by scholars like H.B. Walters, who condemned the barbarity of Roman art when compared to the more refined products of the Greeks (Greene 2005: 37). The focus on the aesthetic aspect of Roman ceramics is a large part of the reason that the study of Roman common wares began so much later the systematic study of finer wares.

In 1879 G. F. Gamurrini published the first study of black gloss vessels found in the western Mediterranean and named them "Etrusco-Campanian" in type. Following this, black gloss received very little attention until Nino Lamboglia's 1952*classificazione preliminare*. Lamboglia identified three fabrics and posited production locations near Naples (Campana A), Etruria (Campana B), and Sicily (Campana C). He also made a simple typological system to delineate the forms found in each fabric. J. P. Morel (1981) complicated this system with an open typology which allowed further types to be added to his categories. His classes are more focussed on the details of design (open versus closed form, rim shape), rather than on function. The groupings are based on the idea that the potters of a particular series were all aiming to make an "ideal type" and the variations they produced were as close as they could get to that ideal.

When it comes to non-fine wares, the focus of study has taken two different tracks. First, the systematic study of transport amphorae began in the late nineteenth century, spurred largely by epigraphers interested in the appearance of the painted inscriptions on amphorae. R. Schöne (1871), A. Mau (1898), and H. Dressel (1891) established the first typologies of amphorae produced in the Roman Mediterranean (Peacock 1982: 3).

On the other hand, it was only in the mid-twentieth century that attempts were first made to treat domestic common wares as a category worthy of careful study. Nino Lamboglia's 1950 publication of the utilitarian pottery from Albintimilium is an excellent early example which is still often referenced. Part of the difficulty in the study of common wares is the fact that they are often locally produced. Therefore, typologies based on forms may only be relevant for small regions. More recent studies have attempted to organize these wares by broad functional type or by fabric. The introduction of petrological analysis to Roman pottery studies in the 1970s driven by the work of David Peacock began a quiet revolution in the study of coarse-bodied ceramics including amphorae (Peacock 1977; Peacock and Williams 1986).

In 2003, Gloria Olcese and her collaborators created broad regional "type guides" for common ware produced in Italy from fourth to the first BCE (Olcese 2003). Her typology takes fabric into account and allows for significant variation within the form of each vessel. This study is also the first to combine large-scale XRF (energy dispersive X-ray fluorescence) and petrological analysis

with traditional morphological analysis. The intention behind such work is to be a starting point to examine the presence of Italian coarse wares outside of Italy. This could not be done without first a clearer understanding of what was being produced in central Italy itself.

Key Issues/Current Debates

Several interrelated issues in Roman ceramic analysis have been raised recently in the scholarly literature. The primary purpose of initially creating ceramic typologies was to date archaeological stratigraphy. This purpose remains; however, the concern now is that although our understanding of typological development may be correct, our absolute and even relative dates for whole classes of material may be seriously flawed. For material in the Republican period, this could be especially true for black gloss ware. The increasing recognition of the complexity of black gloss production and the growing house of cards of sites dated using black gloss and sites dated using the dates of other sites mean that the revision of black gloss chronology would have significant consequences for Republican archaeology. Furthermore, as our understanding of the use-life of ceramic material and the formation processes of Roman archaeological sites develops, we discover that the production date of ceramic material differs greatly from the date of the use and deposition of various ceramic classes.

Related to this issue of redating is the issue of cost, value, and reuse of ceramics. The interrelationship between ceramic vessels and vessels made of other materials – glass and especially metal – is something which we can only estimate. It was in the middle Republican period that widespread experimentation with different raw materials and form began. Since so few metal and glass vessels are attested in the archaeological record when compared to pottery, our understanding of the economic and cultural value of ceramic vessels might be quite skewed. We wonder who the customers were for fine ceramics – the wealthy upper class? The second-tier moneyed class who could not afford metal wares? Recent scholars have used a combination of ancient literature and quantitative and qualitative material studies to consider this question (Lund et al. 2006; Roth 2007). The study of ceramic repair (pot-mends), use-life, and reuse can help illuminate some sense of the value of ceramic vessels. The work of J. T. Peña highlighting reuse (especially in the case of Roman amphorae) and modeling the ceramic cycle has been quite important to the increased consideration of the multifunctionality and use-life of Roman ceramics of various classes (Peña 2007). These types of studies are being taken into consideration for the redating and better understanding of the complexities of typological change and influence, and indeed site chronology.

The application of archaeometric study to Roman ceramics has also been adopted in the last 25 years. Determining ceramic provenance of coarse-bodied wares (common wares and amphorae) through petrology and XRF and of fine wares through neutron activation analysis (NAA) and chemical testing has both confirmed earlier assumptions about provenance and trade and greatly altered how we understand the movement of raw clay and completed vessels in the Roman world. The employment of archaeometry has allowed for the increasingly systematic study of common wares as well as the expansion and refinement of pottery's role in the Roman economy (Greene 2005). Residue analysis has also been applied to Roman ceramics, especially in Roman Britain, in order to better understand food production, storage, and consumption as well as to examine the reliability of textual sources in our study of ceramic function (Cramp 2008).

The interrelatedness of these issues and the increasing collaboration of material scientists, archaeologists, and classicists have also meant ceramology has become both an increasingly specialized and interdisciplinary field.

Future Directions

Future directions for the study of Roman ceramics in the Republican period relate to the concerns of current research both in their increased specificity

and in their broad syntheses. Firstly, archaeometry will continue to play an important role. Defined most simply as the application of scientific methods (including mathematical, physical, and biological sciences) to archaeological materials, the effect of archaeometry on the questions and concerns of Roman archaeology is only just beginning to be felt. The examination of clay composition and provenance with methods like petrology, XRF, and NAA means an increased understanding of the details of natural resource economy (clay and fuel acquisition, movement, contacts and cooperation between regions), potting technology (clay processing, kiln technology), and human capital (workshop organization and output, training methods, potter individuality and identity), not to mention revealing even more about trade connections, market consumption, and consumer interests.

Residue analysis on archaeological ceramics (gas chromatography/mass spectrometry and liquid chromatography/mass spectrometry being two popular methods) has been used only tentatively by Roman archaeologists thus far because of the limitations of its results; however, these methods are being continually expanded and refined by archaeochemists. Furthermore, the increased accessibility and affordability of this technology means it will become a more popular tool to contribute to the study of vessel use. Research questions regarding foodways and subsistence are very much connected to issues of environmental economy, changing landscapes and urbanization, and cultural contact and identity – themes which are key in the Roman Republican period.

The use of archaeometric methods has run parallel to increasingly detailed study of coarse-bodied ceramics – ceramics for everyday use and used by every class of Roman society. In the future, there should be the continued study of these common wares and an increased recognition of typological series and vessel function. This brings us to our second area of future development: full data reporting and contextual analysis. Many past publications of Roman sites have divided artifacts up by type with the ceramics subdivided and separately studied and published by class. Difficulties of funding, time, and loss of interest have often meant that the overall interpretation and synthesis of the site happens before artifact study is finished, with no reference to ceramic artifacts, or not at all. In contrast, interest in the 1980s and 1990s in the quantitative analysis of Roman ceramics stressed the need to consider in detail all the artifacts in assemblages and to select quantitative methods which minimize recovery and fragmentation bias and allow for inter-site comparison. Many of these early studies used clunky project-commissioned computer programs which were not commercially available. Today, the increased use of digital applications in Roman archaeology including increasingly user-friendly statistical software, sophisticated database programs, GIS, and digital publishing means that we can harness technology in order to perform data organization, processing, storage, and dissemination which has been a slow and daunting process in the past. The coalescence of all of these factors (the equal study of all ceramic classes, the use of quantitative methods, digital applications) allows for the simplest development in Roman ceramic study: complete and explicit data reporting and broad site syntheses which are closely tied to the material record. With thorough ceramic study, ceramics can illuminate the archaeological formation processes at work in creating archaeological sites and excavation conditions and contribute to broad contextual concerns like the function of ancient spaces, status, access, discard practices, and the interconnections between individuals, households, sites, and regions.

Ceramics: Scientific Analysis

Bruno Fabbri and Sabrina Gualtieri
Institute of Science and Technology for Ceramics, National Research Council (CNR) of Italy, Faenza, Italy

Introduction

Scientific investigations on archaeological ceramics are carried out with three different purposes:

- Reconstruction of ceramic processing technology, which includes the definition of the type of raw material used, the possible corrections of the raw clay, the shaping technique, the firing system used, the cooking atmosphere and the maximum temperature reached, and the presence of coatings and decorations
- Identification of the production area of artifacts (the study of provenance), which often requires the analysis of possible local clays, with the main aim of contributing to the reconstruction of the routes of trade between different settlements and cultural contexts
- Definition of the conservation state, in order to better address the works of restoration and conservation

Only the analyses applied in the first two cases are dealt with specifically here because the information obtained is strictly relevant to archaeology.

Definition and Key Issues

Analysis of the Microstructure

The microstructure is defined by observation in polarized and transmitted (instead of reflected) light microscopy, using the so-called mineralogical microscope, with enlargements for the most part between 40 and 100 times. To do this, the sample is prepared in section thin enough (about 30 μm) to pass the light.

The observation allows to highlight many microstructural aspects, including:

- Degree of isotropy/anisotropy of the clayey matrix
- Homogeneity/heterogeneity of the clay matrix, such as the presence of argillaceous rock fragments (ARFs)
- Presence of grains larger than a minimum of about 30 μm
- Size distribution of these granules, which can be concentrated in a limited range or fairly evenly dispersed in the range from about 30 μm to maximum size present
- Nature (including any grog) and shape of these granules
- Presence, abundance, and form of any macropores, that is, voids larger than about 30 μm
- Presence, nature (clayey or vitreous), and thickness of coatings, if any
- Microstructure of the coatings, particularly the glazes (gradations of composition, crystalline inclusions, bubbles)
- Presence of cracks or fractures
- Any filling of pores and fractures with material deposited during the burial of the shards

Such information helps to make various deductions, such as the possible use of plastic material to correct the clay, the origin of the ceramic

material (especially for coarse ceramics), and an evaluation of the firing temperature (Montana et al. 2007).

Chemical Analysis

The chemical analysis serves to determine the chemical composition, expressed by the percentage content of chemical elements that constitute the analyzed material: ceramic body, coating, or decoration.

This type of analysis can be performed with different analytical techniques, among which today the most common are:

- Wavelength dispersion-X-ray fluorescence (WDS-XRF)
- Inductively coupled plasma-atomic emission spectrometry (ICP-AES)
- Energy dispersion spectroscopy coupled with scanning electron microscopy (SEM-EDS)

The elements typically analyzed for ceramic bodies and argillaceous coatings are 10 and are generally reported as oxides in the following order: SiO_2, Al_2O_3, TiO_2, Fe_2O_3, MnO, MgO, CaO, Na_2O, K_2O, P_2O_5. For the analysis of the glazes, PbO and SnO_2 are added to these elements. Finally, for the decorations you can add different coloring oxides, such as CuO, CoO, Cr_2O_3, and As_2O_3, as well as Fe_2O_3 and MnO.

The chemical investigation is very important for the provenance studies, especially for ceramics with fine paste (Maggetti et al. 2011).

Mineralogical Analysis

The mineralogical analysis is performed through the X-ray diffraction (XRD) and serves to qualify and semi-quantify the crystalline phases, among which the main ones are quartz, feldspar, calcite, illite, gehlenite, pyroxene, and amphibole. But the list could go on with minerals less frequent or present in small quantities, for example, dolomite, kaolinite, smectite, chlorite, hematite, and rutile.

Some of these minerals are already found in the clays, while others (new-formation phases) are formed during firing. These phases are generated mainly as a result of the destruction of clay minerals and calcite and the subsequent reaction between the remnants of these components, with the formation of different compounds according to the thermal level reached during the ceramic firing. Therefore, knowledge of the crystalline phases present in ceramic bodies is essential for the evaluation of the firing temperature (Fiori et al. 2011) and can also provide useful information in studies of provenance.

Thermal Analyses

The compounds present in the ceramic material, when subjected to heat treatment, may undergo chemical changes. The thermal analyses record any loss of weight (thermogravimetric analysis, TGA) and the absorption or release of heat (differential-thermal analysis, DTA) caused by these reactions. Since the reactions occur in well-defined temperature ranges, the thermal analyses allow recognizing the original compounds.

The information obtained can be used to confirm the results of the mineralogical analysis and the evaluation of the firing temperature. The minerals that are modified or destroyed at a given temperature indicate, in fact, that this temperature was not reached during the ceramic firing (Fiori et al. 2011).

Examples

Sampling

The analytical techniques mentioned above require the availability of a sample taken from the object to be analyzed and brought to the laboratory to perform the different analyses. Therefore, it deals with invasive analyses but also destructive because a variable amount of material is destroyed during sample preparation or during the analysis. When you plan to run some analysis, it is imperative to take this into account (Artioli 2010).

The amount of material to be taken depends on the type of analytical technique used. For example, the preparation of a thin section for observation under a mineralogical microscope requires a fragment of at least 1 cm, indicatively corresponding to 1 g, while the thermal analyses consume only a few tens of milligrams of material.

The amount of sample depends also on the characteristics of the same ceramics that you want to analyze, because the sample for analysis must always be representative of the material under examination. Therefore, the sample to be taken for coarse-grained ceramic pastes should be much larger than that of fine ceramics, regardless of the type of analysis to be performed.

Finally, it is worth clarifying that there are also noninvasive analytical techniques and that often the analyses in this case can be made in situ (Fabbri 2012). Unfortunately, these techniques are not suitable or are not the most suitable for the analysis of ceramic materials aimed at obtaining information useful in archaeological terms.

Ceramics: Stonewares

David Gaimster
The Hunterian, University of Glasgow, Glasgow, UK

C

Brief Definition of the Topic

It could be argued that stoneware was one of the first western European commodities to have a truly global cultural impact. Archaeologically, it is virtually ubiquitous on first contact sites and European colonial settlements and shipwrecks around the world throughout the post-Columbian epoch, particularly those that have a western or northern European connection. Deriving from heaving industrial production, it could be made in large quantities and its robust body made it suited to long-distance trade. A fully fused true stoneware, with a highly vitrified body (porosity of 0.4%) with firing temperature of 1300–1400 °C, emerged as a commercial product in the Rhineland around CE 1300 following over 100 years of proto- and near-stoneware evolution and successful business development. It is no coincidence this development not only coincided with the spread and growth of towns in northern Europe, and hence new markets from c. CE 1200. The colonization of the Baltic rim by western European Crusaders, clergy, merchants, and artisans required the transfer of western European lifestyles and all its physical attributes. Stoneware enabled the Hanseatic trading community to continue to enjoy their accustomed drinking and table customs and other domestic habits overseas. Stoneware was ideally suited to mercantile urban housing with tiles flagged floors, timber furniture, and with defined living space and service quarters.

Stoneware was a robust but lightweight, nonporous, stainless, and odor-free ceramic body that revolutionized domestic life, from the parlor and dining room to the kitchen, cellar, and latrine. According to the archaeological record, German stoneware penetrated the households of rich and poor across the continent of Europe from the

thirteenth century and forms a primary component of the European colonial toolkit from the late fifteenth century onward. Radical refinements in design and technology from the mid-fifteenth century, notably in the introduction of molded relief forms, transformed the status and function of domestic ceramics in western and northern Europe from essentially utilitarian commodities into symbolic artifacts in their own right. The fusion of mold technology and printed propaganda in the sixteenth century further revolutionized the medium though which topical religious and temporal concerns entered the home. These innovations gave the medium a radically new dimension: relief ornament enabled stoneware to compete for the first time in terms of visual impact as well as function in the dining sphere, particularly with metal vessels and decorated glassware. Stoneware manufacturers drew on a wide range of contemporary popular graphic design sources, which could be reproduced at a minimal cost through mold technology on an almost limitless number of vessels. The wide variety of decorative subject matter, ranging from purely ornamental motifs to biblical, mythological, allegorical, armorial to political and religious imagery, transformed stoneware from a primarily domestic commodity into a minor art form. The fusion of graphical reproduction and molded technology enabled German stoneware producers to respond immediately to rapidly changing political and religious loyalties in the development of a new iconographic repertoire during the course of the sixteenth century.

Unlike, say, Italian or Netherlandish maiolica, which is characterized by individually hand-painted ornament, stoneware potters could replicate complex products in bulk – the only investment required at the mold-manufacturing stage. Stoneware rose rapidly in status. A further technological innovation which amplified the effect of the relief-molded decoration was the deliberate introduction of salt into the glazing process during the course of the early sixteenth century. Analysis of wasters from Rhenish kiln sites suggests that this innovation coincided with the increasing use of applied relief ornament at this time. The combined result radically enhanced the symbolic status of stoneware still further. By the end of the sixteenth century, stoneware relief designs were embellished with the use of cobalt paint.

Although fired on a truly industrial scale from the thirteenth century, German stoneware remained an artisanal, workshop-based craft product until the introduction of machine mass-production in mid-eighteenth-century England. Rhenish stoneware potters attempted to replicate Staffordshire tea ware forms but to no avail and, bar a few specialist products, their presence in the international export market ceased abruptly. However, the instrumental role of the historic Rhenish stoneware production in establishing the British and North American stoneware industries of the eighteenth to twentieth centuries is undisputed. Today, German stoneware is regarded as a key artifact type for the archaeology of late medieval and early modern society, and in particular for the study of domestic life, table culture and for trade and long-distance cultural transfer. It is a type-fossil of European settlement archaeology around the globe.

Ceramics: The Ibero-American Shipping Container

Tony Pasinski[1] and Patricia Fournier[2]
[1]Independent Investigator, La Antigua Guatemala, Guatemala
[2]Posgrado en Arqueología, Escuela Nacional de Antropología e Historia, México, DF, Mexico

Introduction

Many goods from Europe were once packed and shipped around the world in a seemingly endless variety of ceramic containers. Today, they can be found at the bottom of almost every body of water that ships crossed and in almost every land on which European explorers, settlers, missionaries, and merchants set foot. To date, the only containers that have received serious study are those that John Goggin (1960) called "Spanish Olive Jars," a term that seems to have caused more problems than it has resolved. He limited his discussion to two varieties: one that is globular and one that has been referred to as "amphora-like," "egg-shaped," "carrot-like," "elongated," and "conical," among others (Fig. 1).

This entry presents the key definitional points and debates that have been published, usually under the English heading "Spanish Olive Jar," the Spanish heading "*botija*," the Portuguese heading "*anforeta/botijuela*" (depending on the shape), and under a variety of different headings by other investigators.

Definition

The earthenware vessels referred to here as "shipping containers" are part of a ceramic tradition dating back thousands of years, which was based on the need to find a low-cost method of safely packing and effectively stowing perishable food stuffs for maritime commerce.

For its colonial, transatlantic commerce, Spain adopted two principal ceramic container forms: one that was globular and one that was conical. Over time, the two handles of the original, globular vessel were eliminated, and the vessel's method of production changed from the suggested preparation of two halves that were joined together to a

Ceramics: The Ibero-American Shipping Container, Fig. 1 Plain *botija* found in excavations at the historic district of Mexico City, probably dating to the 1600s; green-glazed *botija*, private collection

single throwing on a potter's wheel. The conical vessel, always wheel-thrown, experienced significant changes in its size (Fig. 2). The neck rim was always added in the last stage of production, but studies show that its profile, on both varieties, changed significantly over time (Fig. 3). In terms of surface treatments, both varieties have examples with no treatment and examples covered with a lead-based glaze. To date, only some examples of the globular vessel show the application of a tin-based, lead glaze to the interior.

Spanish contracts for the production of ceramic shipping containers used a variety of names to indicate the specific vessel being requested, with no particular description that would indicate their shape (e.g., Gestoso y Pérez 1995). Ship registers, prepared by a large number of notaries, also used a variety of terms when listing the ceramic shipping containers in which goods were packed, again with no indication of the shape (see *Archivo General de Indias*, Section *Contratación*). No clear definition has been made that would establish an exact correspondence of contents to vessel type in terms of elements such as shape, size, name, and glazed/unglazed.

Spanish varieties often have stamped, impressed, embossed, in relief, incised, engraved, scratched, or filed marks on the neck rim or impressed marks on the shoulder (Fig. 4). They may also have "painted" marks on the vessel body. The wide distribution of the same rim mark across a number of disparate archaeological sites in the Americas raises more questions than it answers regarding the significance, if there is one, of these marks, considering their absence on any part of the visible surface of other Spanish earthenwares.

Ceramics: The Ibero-American Shipping Container, Fig. 2 Olive jar styles according to Goggin (*upper* rows, not to scale) and form types as proposed by James (*lower* row). (Adapted from Goggin (1960: 28) and James (1988: 48))

Ceramics: The Ibero-American Shipping Container, Fig. 3 *Botija* rim profiles and styles as proposed by Goggin. (Adapted from Goggin (1960: 10, 13, 19))

Documentary evidence (e.g., Zunzunegui 1965) indicates that both vessel varieties were wrapped in a protective matting of woven bands of esparto grass to which two handles were attached, using the same material.

Data from ship registers indicate that wine and olive oil were always a cargo item on each ship. The two products were packed, but not exclusively, in the globular or conical ceramic containers. They also indicate that the following list of products could, from time to time, be packed in the same kind of containers: vinegar, honey, olives, almonds, capers, chickpeas, hazelnuts, rice, tuna, myrrh, various types of fragrant oils, raisins, figs, eggplant, flour, pitch, soap, brandy, lard, gunpowder, and the accompanying, round, lead shot for firearms (e.g., James 1988; Velasquez and Fournier in press). However, register entries mentioning these products also indicate that they were shipped in barrels (a preferred method for some items) or in other types of ceramic containers for which there are no descriptions.

Spanish ceramic shipping containers were recycled both in Spain and in its colonies. In Spain they were used as filler material in walls and as structural support in the construction of vaulted ceilings, and they were sometimes buried below floors to prevent ground moisture from seeping up (Amores Carredano and Chisvert Jiménez 1993). In the colonies they served the same purpose but were also used in domestic contexts for storing water, beer, and certain dry goods, such as flour, corn, and beans, and in military contexts for storing water. They may also have served to pack New World exports, such as pearls

Ceramics: The Ibero-American Shipping Container, Fig. 4 *Botija* rim marks from archaeological samples found in the former monastery of Santo Domingo, Guatemala (*upper* rows), and in different excavations at the historic district of Mexico City (*lower* two rows)

Ceramics: The Ibero-American Shipping Container, Fig. 5 Example of a small Peruvian *botija* from monastery of Santo Domingo (Guatemala). The mouth rim was reworked in the recycling process to make it larger

from Venezuela and *bálsamo* (balm) from Central America, for shipment to Spain.

Portugal, on the other hand, adopted and tended to maintain a wheel-thrown, globular, two-handled vessel for its oceanic commerce. However, archaeological evidence from the wreck of a Portuguese vessel off the coast of Mombasa, Kenya, appears to indicate the introduction of an elongated, two-handled version not previously mentioned (Sassoon 1981). To date, none of the vessels show indications of glazing. There is no evidence that these vessels were known locally as other than *anforetas/botijuelas* that they had rim or shoulder marks or that they were wrapped in matting. No studies have indicated changes over time to the triangular-profile, neck rims. The only products known to have been shipped in them were wine and olive oil, destined for merchants in northern Europe, in Newfoundland, in present-day Canada, and probably African or Asian Portuguese settlements. There is no evidence of recycling; in fact, they are reported as having been thrown away when empty (Newstead 2008). The "amphora-like" vessel called *anforeta* appears to be of Spanish origin.

The introduction of wine industries in some of the Spanish-American colonies appears to have created the need for the local production of ceramic containers in which wine could be distributed. Evidence has been published recently that shows that *botijas* were definitely produced in at least Peru's Moquegua wine region (e.g., Rice 2010: 44, Fig. 9) (Fig. 5), in the Mendoza region of Argentina (Ceruti 2005), but only possibly in present-day Chile (e.g., Lacoste 2007).

Peruvian wine appears to have had a wide distribution. *Botijas* from that colony have been found in Panama (Rovira 1983: 24) and in Guatemala. One example has been located on an island in the South Pacific, believed to have been brought on a ship that set sail from Peru to explore that part of the world (Bedford et al. 2009: 82, Fig. 2).

Published photographs indicate that the conical vessels were long and wide, had no neck rims, and were stoppered with something other than cork. Unpublished physical evidence from Guatemala shows that there were two sizes. The smaller

vessel had a length of at least 51.5 cm and a diameter of 29.3 cm. The larger vessel had a length of at least 91.2 cm and a diameter of 40.8 cm. Both vessels had wall thicknesses ranging from 2.5 to 3.0 cm. The interior of the wall was covered with pitch. Like Spanish *botijas*, they were recycled, but to do so it appears that the recycler reworked the mouth opening to make it larger. Oral tradition in Guatemala suggests that these reworked Peruvian *botijas* were set into the ground and used for fermenting clandestine liquor. Their sheer weight probably precluded them from being used in vaulted roof construction.

The early planting of olive trees in Peru seems to have resulted in a high level of local olive oil production prior to 1650 and the need for *botijas* in which to pack and distribute the oil. If those *botijas* have been found, they have not been identified as non-Iberian.

Current Debates

The current debates on ceramic shipping containers can be framed in terms of four perspectives: (1) defining the types of vessels that represent the full range of ceramic shipping containers; (2) finding an agreed-upon nomenclature for this group of vessels, which could be translated and understood easily from one language to another; (3) discovering the centers of production and determining the ceramics ecology involved in the production process of each vessel type; and (4) determining the processes followed to fill them and to transport them to ports for maritime shipment or to commercial centers for overland transport within a specific region. The level of these debates varies by investigative area.

Spanish America

The Spanish "ceramic shipping container" has undergone considerable archaeological debate within the realm of Spanish-American archaeological studies since 1960, when John M. Goggin (1960) gave it a ceramic-type name "the Olive Jar" and provided a definition, a description, and a dating chronology. However, he made four things clear: (1) his work was "an initial contribution"; (2) he found fragments of "extremely large vessels" with olive jar paste and neck rims similar to those of his studied vessels, but that he excluded them; (3) "olive jars... are a useful time marker for... a primary Colonial situation or in an aboriginal contact situation... Other Spanish ceramics, such as majolica, are more precise time markers"; and (4) they are sturdy vessels that can be seen still – used for multiple domestic purposes in Latin America.

In summary, through his investigations in Spanish colonial sites in and around the Caribbean, he divided his olive jar findings into three datable styles: Early (CE 1500–1580), Middle (CE 1580–1800), and Late (post CE 1800); and into four vessel shapes: A, B, C, and D (Fig. 2). Within each style/shape combination, he noted that the profile of the vessel's rim changed (Fig. 3). He made no attempt to date those changes nor suggested that there might be some significance associated with those changes.

It was through subsequent investigations that debates were opened regarding Goggin's findings. They began with Zunzunegui (1965), who expanded upon Goggin; were continued by James (1988), Marken (1994), and Avery (1997), who questioned some of his findings; and have been kept ongoing by many others (e.g., Carruthers 2003; Velasquez and Fournier in press).

There appears to be no consensus on the definition of a colonial, ceramic shipping container. If, in Greco-Roman times, it was defined by the "carrot-shaped" amphora, Goggin accepted that in his study but was forced to include the globular vessels also used in Spanish colonial, maritime commerce. Subsequent writers have brought into the discussion flat-bottomed containers, with their myriad of shapes and sizes (e.g., James 1988; Marken 1994).

There is still some question about the manufacturing process for the earliest globular vessels (two sections or a single wheel throwing) and for the large conical vessels, as well as the process followed to "add" the neck rims of both varieties (e.g., Avery 1997).

There is no consensus on a name for the vessels. Goggin established "olive jar" as his translation of the Spanish term *botijuela*, which appears in colonial Spanish documents. Therein lies the problem. *Botijuela* is the name of the container,

without reference to its use or future contents. Perhaps for this reason, as time passes, English speakers seem to be coming more comfortable with using the Spanish term *botija* when discussing ceramic shipping containers made in Spain and Latin America.

From the number of proposals presented, a seemingly endless list can be made of the products that may have been packed into Spanish ceramic shipping containers. For many of the proposals, arguments have been put forward clearly refuting them, resulting in no clear definition. Only Avery (1997) appears to have attempted to analyze changes over time – from the use of ceramic containers to non-ceramic and vice versa.

Suggestions have been put forward, but an agreement has yet to be reached on the significance, if any, of the marks placed on the rim or shoulder and/or "painted" on the body of Spanish vessels, something that has not been noted on vessels produced in other countries.

Spain

Goggin knew that the manufacturing center for the ceramic shipping containers he discussed was Spain, in particular the area in and around Seville. Spanish archeologists do not disagree, but they claim that they have problems applying his work in their country. From evidence found in datable architecture, Amores Carredano and Chisvert Jiménez (1993: 306–11, Figs. 39–88), for example, eliminate the Early Style round vessel from Goggin's list, saying that it is a *cantimplora* (canteen) not a *botija* (Amores Carredano and Chisvert Jiménez 1993: 281). They eliminate the Middle and Late Style designations for the conical vessel, saying that the two existed simultaneously (Amores Carredano and Chisvert Jiménez 1993: 284). They add to Goggin's list the flat-bottomed vessels discussed in James (1988: Fig. 4) (Fig. 2) and add two more with the same basic form but with handles (Amores Carredano and Chisvert Jiménez 1993: Figs. 84–88).

Portugal and Its Trade Routes

Goggin did not investigate or consider Portuguese examples of ceramic shipping containers. Thus, his work is of little use to investigators working in Canadian sites that traded with Portugal or in West African sites that were on Portugal's trade route to the Orient. Portuguese shipping containers have been found in both areas. They may be present in Japan. Surprisingly, they are reportedly absent from Portugal's own archaeological sites. Current debates are of an investigative nature, using the *anforeta/botijuela* as an element in defining the extent of Portuguese colonial trade networks.

Peru, Argentina, and Chile

As with Portugal, the debates in Peru, Argentina, and Chile are investigative, focusing on finding the production centers, defining the forms, and understanding the extent of their respective distribution networks.

Future Directions

Olives, olive oil, and wine were characteristic of Mediterranean cuisine. As a result vines and olive trees were brought to the Iberian colonies in the New World, and wine and olive oil industries developed in several regions of the Americas in the 1500s. However, most were either unsuccessful or banned by Crown policies protecting domestic production and exports to the colonies. Notable exceptions were the wineries in South America, for example, in the Peruvian Moquegua Valley (e.g., Rice 2010), supplying consumers at mining towns such as Potosí in modern Bolivia.

In Spanish-American colonies, the incorporation of indigenous material culture was partial, and Old World food and drink as commodities remained as signifiers of group culture and identity. The so-called olive jars as containers were mainly used for storage and for transporting goods by sea from the Iberian Peninsula to the Americas, Africa, and Asia, where they were reused as containers or for architectural purposes, where they were used to lighten the weight of vaults and as fill in floors.

They represent, to a certain extent, evidence of consumption trends among colonists of European descent who replicated foodways from the homeland, as well as colonialism processes and the rise of the modern world system.

Additional research is needed on samples from the Iberian Peninsula and sites all over the world

where fragments of the ubiquitous shipping containers have been found, especially compositional studies by means of neutron activation analysis. Petrography may also be used but, so far, the results have not proven to be accurate enough to determine production locales. Future studies may provide direct evidence for site-specific production, identifying manufacturing centers with more precision, as well as the ancillary industries such as those producing the matting used to protect the vessels during transportation, thus furthering our knowledge of trade networks largely controlled by the Iberian monarchies from the late fifteenth to the early nineteenth century.

Chaco Canyon, Archaeology of

Stephen H. Lekson
University of Colorado, Boulder, CO, USA

Introduction/Definition

Chaco Culture National Historical Park, in northwestern New Mexico, USA, preserves the ruins of eight major and many smaller "Great Houses" (Lekson 1986) – large, impressive masonry buildings which represent a critical, eleventh-century-CE episode in the prehistory of the Pueblo Indian tribes and other native groups in the US Southwest (Fig. 1). The largest Great House, Pueblo Bonito, was a giant "D"-shaped building with carefully crafted sandstone walls standing five stories tall. Its 600-plus rooms and enclosed plaza cover almost one hectare. The Great Houses were built with an investment of labor and a precision of form seldom seen at other Southwestern sites. Tens of thousands of wood beams for roofs were carried into Chaco from distant forests; many hundreds of laborers marshaled for construction events. The Great Houses were planned as defined geometric forms, skillfully aligned to the sun, moon, and cardinals (Fig. 2). Excavations produced extraordinary assemblages of artifacts, of Southwestern and Mesoamerican origins. Impressive numbers of pots, lithic materials, foodstuffs, and so forth were brought to Chaco from substantial distances. (This essay is based on data summarized in Lekson 2006, 2007, 2009; see also Vivian 1990; Mills 2002; Noble 2004; Van Dyke 2007; Chaco Research Archives 2012).

Chaco Canyon, as a UNESCO World Heritage Site, is a major tourism destination within the US Southwest. In part, Chaco's attraction is its improbability, an unlikely setting for such impressive ruins (Fig. 1). Chaco Canyon is a remote, unremarkable, sandstone canyon with few resources. Water is scarce, wood for construction and fuel is (and was) almost nonexistent, and the canyon is a poor place for corn (maize) farming – the key crop of Chaco's times. Yet, Chaco's ruins are the largest, most famous monuments in the US Southwest. Great Houses at Chaco represent something of a "mystery" – a mystery polished by the popular press, by local heritage tourism industries and New Age communities, and – to some extent – by archaeology.

Key Issues/Current Debates

Archaeological research began at Chaco in the late nineteenth century and continued, with occasional pauses, to the present (Lister and Lister 1981; Frazier 2005). The ruins were originally interpreted as "Pueblos" – independent, egalitarian farming villages, much like those of modern Pueblo Indians in New Mexico – curiously jammed into an improbable canyon. By the 1950s, the "Pueblo" view was no longer tenable (Vivian and Mathews 1965): Chaco was not a canyon of "Pueblos"; rather, Chaco was a complex settlement of many differing structures and edifices. Great Houses contrasted sharply with far more numerous, normal family houses (six rooms and a "kiva"). The total floor space of a normal house was about equal to a single room at Pueblo Bonito. Chaco Canyon, while dominated by Great House ruins, was home to hundreds of normal families. Based on burial data, the Great House residents were of markedly higher status (Akins 2003; Plog and Heitman 2010). The variety of structures suggests a polyglot, multiethnic population (Vivian and Mathews 1965). Moreover, tree-ring dating (developed in part at Chaco in the 1920s) demonstrated that Chaco was alarmingly early, dating to the eleventh and early twelfth centuries CE, compared to the thirteenth-century-CE cliff dwellings of Mesa Verde and later iconic ruins.

Research in the 1970s revealed Chaco as a regional center, its hinterlands defined by 150 smaller Chaco-style Great Houses scattered over an area the size of Ireland, densely dotted with thousands of normal homes. Normal homes housed 95% of Chaco's people; less than 5% lived in Great Houses. Chaco's region was held together, symbolically and materially, by an unprecedented network of "roads" (yet Chaco

Chaco Canyon, Archaeology of, Fig. 1 Chetro Ketl, the second largest Great House at Chaco Canyon. Constructed 1000–1125

lacked wheels and beasts of burden) and by an extensive line-of-sight signaling systems. The roads and signaling systems, radiating out from Chaco Canyon, linked distant Great Houses back to the center. Chaco's region is gratifyingly clear, and Chaco Canyon was clearly its center. Pueblo Bonito, it seems, was but one element of a 10-km diameter aggregation of Great Houses and normal homes, platform mounds, and other monuments, built to an urban plan that almost certainly reflected Chaco cosmology, on monumental scales (Van Dyke 2007).

Chaco's archaeology far exceeded anything archaeologists expected to see in the Pueblo Southwest. Chaco became a "phenomenon" or, more recently, a "mystery." Archaeology, to some extent, fosters that "mystery": Chaco scholars offer a bewildering range of interpretations, leading many to conclude that Chaco must remain unsolvable – and, therefore, mysterious.

Current interpretations form three themes: Chaco as Pueblo, Chaco as Uniquity, and Chaco as Polity. "Chaco as Pueblo" maintains that Chaco – whatever it was – will best be understood through the lens of Pueblo ethnology and traditions (e.g., essays in Ware 2001; Mills 2004; Noble 2004; Fagan 2005). Ethnographies and Pueblo traditions both provide significant insights, but Pueblo ethnographies and Pueblo traditions have no place for a predominant regional center – each Pueblo is independent and owes nothing to other Pueblos save benign ties of kinship and ceremony. Pueblo life revolves around ritual and ceremony, to the exclusion of centralized power. Pueblos are famously egalitarian; Chaco was not.

"Chaco as Uniquity" recognizes several interesting, if slightly outré, interpretations which see Chaco as something previously unknown in the Southwest – but still congruent with Puebloan emphasis on ritual and ceremony. For example, Chaco as a pilgrimage center: an empty valley periodically thronged by pilgrims, much like Mecca (Malville and Malville 2001). That

Chaco Canyon, Archaeology of, Fig. 2 Ground plans of major Chaco Canyon Great Houses

interpretation is widely accepted. Mecca, however, and most New World pilgrimage centers were bustling cities, for example, Cholula, the preeminent pilgrimage center in ancient Mesoamerica. Chaco may have served as a focus for pilgrimage but probably not as an empty ceremonial center – in short, a uniquity.

Before accepting unique interpretations, consider a better grounded alternative: "Chaco as Polity." North America in Chaco's time was awash with "chiefdoms," city-states, and empires; that was Chaco's world, the context in which Chaco rose and fell. And Chaco has all the hallmarks of a political capital, a seat of power. Great Houses are quite obviously elite housing (and more, of course). Chaco's control of labor and materials (quotidian and prestigious) would be notable in a (small) Mesoamerican capital. Indeed, that is what Chaco was: "Chaco as Polity" – or, rather, "Chaco as [Mesoamerican] Polity." Not a polity created by Mesoamericans but a local manifestation of a Mesoamerican ideal. The typical Mesoamerican polity was a small city-state or (in Nahua) *altepetl*: an association of a half-dozen or more noble families, each with its own palace ("noble house") in the central capital – which could be surprisingly small, Chaco-sized (Hirth 2003; Smith 2008). The noble families were equal; they elected from their ranks a king who ruled for life and later elected his replacement. City-states typically had from 10,000 to 40,000 commoners (Hodges 1997: 218; Smith 2008: 90), and each commoner family was tributary to a particular noble family or lineage. Indeed, the relationships of nobles and commoner defined the *altepetl*.

That model fits Chaco like a glove: a small city of perhaps 2500 people (about one-third of documented *altepetl* capitals were under 3000; Smith 2008: 152), dominated by eight Great Houses and many lesser monuments, with roads radiating out into pie-chart hinterlands encompassing – at a guess – around 50,000 commoners (a guess, but a good guess). The basic model and the demographic scales are consistent with *altepetl* organization; the major difference was regional scale. Most Mesoamerican polities were small, perhaps 50 km in diameter. Chaco reached ten times that far, with outermost Great Houses 250 km from the center. The difference lies, almost certainly, in the productive challenges of the desert Southwest compared to the tropical luxuriance of Mexico. In Mesoamerica, lots of food could be grown in relatively small areas; in the Southwest, arable lands were limited, patchy, and scattered. Chaco invented or adopted technologies to adapt *altepetl* organization to its deserts: roads and signaling systems overcame distances.

This is not to say that Mesoamerican nobles created Chaco. Rather, Chaco nobles-manqué adopted Mesoamerican forms. To legitimize their status, they probably visited southern (see Helms 1988). Chaco elites employed Mesoamerican objects and ideas (for example, macaw feathers, copper bells, and colonnades); they drank cacao (Crown and Hurst 2009). It is useful to imagine that Chaco elites considered themselves "Mesoamerican" (or whatever the appropriate term for Chaco's time) – that was, after all, their world, their frame of reference. In any event, Chaco elites adopted or coevolved a ubiquitous Mesoamerican form for their local polity: Chaco was an *altepetl* city-state.

Questions of this sort are often framed as discrete Mesoamerican "influences" in a conceptually distinct Southwestern region; but surely, it is more realistic to consider the US southwest as a northwestern frontier of Mesoamerica. Current archaeological frameworks perpetuate the separation of US and Mexican prehistories by a colonial border created by a war waged in 1846–1847. That border did not exist in Chaco's time. Accepting a more realistic framework for the question renders Chaco far less mysterious but no less interesting.

Construction at Chaco Canyon ended around 1125 CE. Not coincidently, a new capital rose at Aztec Ruins, about 60 km due north of Chaco about 1110 CE. That capital flourished for a generation; a major drought from 1130 to 1150 started a chain of events that culminated in warfare and the collapse of Aztec Ruins and the abandonment of its region, which included the cliff dwellings and towns of Mesa Verde.

Chaco Canyon (as "White House" and other names) figures in many Pueblo traditional histories, and Pueblos claim it as an ancestral site. The Navajo Nation includes several clans with strong claims to Chaco. Chaco has other constituencies; it was a major site of the New Age "Harmonic Convergence" of 1987, and it appears prominently in current chatter about the "Maya calendrical cycle" of 2012. With a remarkable flurry of publications and videos in the early 2000s (e.g., Fagan 2005), Chaco has probably supplanted Mesa Verde as the most famous site in the US Southwest.

Chaloupka, George

Margie West
Emeritus Curator Aboriginal Art, Museum and Art Gallery of the Northern Territory, Darwin, NT, Australia

C

Basic Biographical Information

George Jiri Chaloupka (1932–2011) was the Northern Territory's leading rock art specialist who advocated the critical need to preserve what he called the largest and most important rock art assemblage in the world. He grew up in the small town of Týniště nad Orlicí in Bohemia Czechoslovakia, shortly before its Nazi occupation between 1938 and 1945. Three years after this, Czechoslovakia's fledgling democracy was destroyed by a communist coup d'état that George desperately wanted to escape. So he and his brother Milo fled separately and were eventually reunited in Perth, Western Australia, after George arrived in 1950 as an assisted refugee. In Perth, George met Indigenous members of the Coolbaroo League and soon married Janet Davey whose sister Maureen married Milo. In 1956 they all set out to see the Melbourne Olympic Games, taking a circuitous road trip via Darwin in the Northern Territory. George instantly fell in love with the tropical climate and the vibrant multicultural society of this remote capital along with Janet, who felt her Noongar Indigenous

heritage could be accepted here for the first time. Darwin subsequently became the couple's lifelong home along with their children Roman, Evelyn, and Pearl.

George's first job in 1956 was working as a government hydrologist for the Water Resources Branch, investigating remote rivers and watercourses like the East Alligator River system where he saw his first Aboriginal rock painting. It was an epiphany for George who recalls, "I stood spellbound by their magic, captivated by their unique form and the brilliance of their execution" (Chaloupka, George, 1993. Journey In Time, p. 8).

Although he had no formal qualifications, George started locating rock art galleries in his spare time and, given his growing reputation, was later employed in 1973 as a Field Researcher then Curator of Rock Art at the Museum and Art Gallery of the Northern Territory (MAGNT). From then on he dedicated his life to recording the region's rich rock art heritage and after his retirement in 1997 continued on as the Museum's Emeritus Curator of Rock Art. When he passed away in 2011, he was honored with a state funeral in the Anglican Church where he designed the contemporary stained glass window after Cyclone Tracy.

Major Accomplishments

George Chaloupka made a significant contribution to the study of Australian Aboriginal rock art that was still in its developmental stage before he arrived in Australia. As one of the first researchers to continuously engage in one art region over a long period of time, he established the distribution, diversity, and richness of a regional corpus of rock art by recording close to 3500 art sites in western Arnhem Land. These were often in rugged, remote parts of the escarpment only accessible by helicopter or on foot.

He also researched the art's continuing sociocultural significance for the various resident Bininj groups of the Arnhem Land Plateau and formed enduring friendships with traditional owners such as Nipper Kapirigi, Namingum, Bill Neidjie, and Bardayal Nadjamerrek among many others. In 1996 he honored his friend Nadjamerrek, with an interactive CD "Angkung Kunred, Wild Honey Country" documenting the artist's deep cultural knowledge of his clan lands.

George also recorded the rock art in other regions in the Northern Territory, including in Wardaman country near Katherine that is featured in the 1987 film "Land of the Lightning Brothers." This followed his film "Images of Man" on the rock art of Arnhem Land. He also produced a series of important research papers, lavishly illustrated reports, as well as his most significant publication on western Arnhem Land rock art, "Journey in Time." Throughout much of his professional career at MAGNT, George was aided by rock art assistant Pina Giuliani, who later became his second wife.

In films and publications, he promoted the beauty and significance of rock art and fought passionately for its conservation. Over the course of several decades of fieldwork, he built up a nationally important archive of images and their location, field notes, and uniquely important Indigenous accounts of the rock art, now held by MAGNT. He's probably best known for his proposed sequence of phases and changing art styles over a 50,000-year period, arguing for the deep antiquity of Kakadu rock art. He set out the first version of his rock art sequence at an Australian Institute of Aboriginal Studies conference in Canberra in 1974 at a time when detailed regional studies of style and sequence were unusual and before Lesley Maynard's seminal work put rock art studies on a new footing. Although George's strict linear chronology of stylistic sequences has since been critically revised by researchers such as Darrel Lewis and Michael Morwood, it exemplified his artistic approach to rock art which he declared could not be reduced to quantified analysis. This was quintessential George, with his irrepressible artistic temperament also expressed through his love of painting which he pursued in his home studio whenever he had time.

Throughout his life, George was also an outspoken advocate for Indigenous rights, and his opposition to uranium mining in the west Arnhem region was one of the factors that stalled Pan continental's plans to develop the Jabiluka mine. In 1978, he nominated the Djawumbu massif for

the Register of the National Estate and provided important anthropological information to the Aboriginal Land Claim that culminated in declaration of Kakadu National Park (Stage 1) in 1979. In this way he repaid his considerable debt to his Indigenous friends.

Awards

George was recognized during his lifetime for his considerable contribution to rock art research. He was the Inaugural President of the Australian Rock Art Research Association, won a Churchill Fellowship in 1983, was a recipient in 1986 of a research grant from the Australian Institute of Aboriginal and Torres Strait Islander Studies of which he was a member, and was a visiting fellow at the Department of Prehistory in the Research School of Pacific Studies at the Australian National University. He received an Order of Australia in 1990, was elected an Honorary Fellow of the Australian Academy of Sciences in 1997, received a Doctor of Letters from NTU (now Charles Darwin University) in 1998, and was awarded a Centenary Medal in 2001. In 2008 the MAGNT Foundation established the George Chaloupka Fellowship in his honor to promote and support the ongoing research and conservation of Aboriginal rock art. He would have approved of this initiative, having once commented, "I'd sell my soul to the devil for another lifetime. There are thousands of sites still out there that I will never see" (Smith, Mike, 2012, p. 134).

C

Chami, Felix Arkard

Herman Ogoti Kiriama
Kisii University, Kisii, Kenya

Basic Biographical Information

Felix Chami (1958–) a third child of coffee farmers, Arkardi and Rosalia Chami, was born in the Hai area of the Kilimanjaro Region of Northern Tanzania, an area occupied by the Chagga community. His parents being staunch Catholics, Chami professes the same faith. Felix is married to Evalista Chami, and they have three children.

Felix attended Ulali Primary School and later Maua Franciscan Seminary both in the Kilimanjaro Region before proceeding to Ilboru High School in the Arusha Region for his advanced secondary education. Thereafter he joined the University of Dar-es-Salaam where he graduated with a BA degree in sociology. After Dar-es-Salaam, between 1986 and 1988, he proceeded to Brown University in the USA for his MA Anthropology. It is at Brown that Chami first came into contact with archaeology, a discipline he liked and majored in. His major interest was in

the Iron Age of East Africa, and his dissertation was on the Early Iron Age of Limbo district on the Tanzania Coast. Between 1989 and 1988, Chami attended Uppsala University in Sweden for his PhD. This is where he refined his arguments on the East African Iron Age, and in his PhD thesis, he revolutionized the thinking that was then prevalent in the region regarding the Early Iron Age. He, for instance, showed that Kwale ware, which hitherto had been shown to be restricted to the coastal areas alone, was not so, that indeed it would be found even on the East African hinterland, and also that it was not homogenous as other scholars had previously argued. Chami also was instrumental in showing that the seventh-century local pottery previously known as Tana Ware and ascribed to the pastoralists was indeed associated with farming communities, and he argued that since incised triangles were the dominant motif and technique on these ceramics, the ware should be renamed Triangular-Incised Ware (TIW), a name that is used currently (Chami 2008a).

Felix started his working career as a tutorial assistant at the university of Dar-es-Salaam in 1986 before moving up the ladder and becoming a full professor of archaeology in 2003. Chami has also held visiting professorship in a number of universities that include the universities of Zimbabwe (2000); Bristol, UK (2002); Ulster (Coleraine) (2003); Legon, Ghana (2009); Comoro (2009); and INALCO, Paris (2010). He was also a visiting fellow at the Indian Archaeological Association Delhi/Allahabad Museum in 2004.

Other than his teaching responsibilities, Chami was, between 2003 and 2012, the general coordinator of the African Archaeology Network (AAN), a group of African archaeology scholars, and was in 2011 elected as a member of the UNESCO International Scientific Committee of the Slave Route. Chami is a member of several professional organizations that include the British Institute in Eastern Africa, Tanzania Association of Archaeologist and Paleoanthropologist, Historical Association of Tanzania, Society for Arabian Studies, African Archaeology Network, and Society of Africanist Archaeologists (SAFA).

Major Accomplishments

Chami can be said to be one of the new crops of African archaeologists who started questioning the paradigm that had existed in African archaeology for a long time; that, for instance, there was no connection between the coastal communities and those in the hinterland because the coastal communities were outward looking and therefore foreign (Chami 1992, 1994–1995). In his Masters and PhD dissertations, Chami, for instance, showed that the pottery type known as Kwale ware and ascribed to the Early Iron Age using communities was not only a coastal phenomenon but also was to be found in the interior (Chami 1994). Chami critically analyzed the mid-first-millennium CE pottery type known as Tana Ware and concluded that, unlike what was previously argued, this ware did not belong to the coastal pastoral group but was a development out of Kwale ware and because of the predominance of incised triangles, he renamed it Triangular-Incised Ware (TIW), a designation that is now widely used.

Chami also argued and backed with evidence the existence of the earliest settlements on the islands of East Africa dating back from the Earlier Stone Age through the Neolithic period (Chami 2009a, 2009b). He has examined issues of slave trade and excavated Bagamoyo, one of the slave-trading towns of Eastern Africa. He has also demonstrated the existence of Egypto-Greaco-Roman trade with the eastern African Indian Ocean settlements (Chami 2011b, 2017). Chami has also looked at the issue of equifinality and its application to African archaeology and argues that archaeology is archaeology and nothing else; borrowing from other disciplines does not change what archaeology is (Chami 2007, 2008b, 2011a). He has published a number of books, the most recent ones being *Zanzibar and the Swahili Coast from 30,000 Years Ago (2009)* and *The Unity of African Ancient History (2006)*. His work contributes to a better knowledge of the slave trade in this region through archaeological evidence (Chami 2008b).

Champollion, Jean-François

Joanna Dębowska-Ludwin
Departament of Egyptian and Near Eastern Archaeology, Institute of Archaeology, Jagiellonian University in Krakow, Krakow, Poland

Basic Biographical Information

Jean-François Champollion was born in 1790 in Figeac, Midi-Pyrénées, France. He spent his early years in the family house surrounded by books hidden for the time of the French Revolution by his father, a former bookseller. However, the most important for the education and later Champollion's career was his older brother, Jacques-Joseph Champollion-Figeac (as he signed his works in contrast to the younger Champollion *le jeune*), who became his first teacher, counselor, and guardian and even the editor of Champollion's texts after his premature death.

Champollion was a genially talented linguist and historian and a pioneering archaeologist, who – apart from his works – left many private letters illustrating his ideas, passions, and difficult character: straightforward, proud, self-confident, and even impertinent. He studied Latin, Greek, Hebrew, Arabic, Ethiopian, Chaldean, Coptic, Chinese, Zend, Pahlavi, Farsi, etc., but his extraordinary talents manifested already around the age of 6, when Champollion taught himself to read. At a high school in Grenoble, he demonstrated genial results in the fields of ancient history, geography, and languages, especially in Coptic, the language that became his second preferable. On the other hand, young Champollion completely disregarded sciences, feeling almost physical pain being forced to study subjects like math. To continue his studies, he moved to Paris in 1807, where at the School of Oriental Languages he met Silvestre de Sacy. Around this time Champollion made his first attempt to decipher the Rosetta Stone but stacked adopting wrong hypotheses and left the idea in 1809 (the year he was appointed an auxiliary professor of ancient history in Grenoble) to finally return to it in 1814. The work had to be postponed when Champollion engaged into the Napoleon's Hundred Days, what resulted in an 18-month exile to Figeac, a difficult period of family tensions and political repressions that – paradoxically – gave the essential rest before the final progress on decipherment of the Egyptian hieroglyphs.

From 1817 to 1821, Champollion lived in Grenoble again, where facing many difficulties he only found a post of a teacher. It was also the time when he decided to marry Rosine Blanc (the couple had only one daughter, Zoraïde, born

in 1824). And once again Champollion's rebellious heart and politics forced him to change his life and move back to Paris in 1821. Without any outcome, dependent on financial support of his generous brother, Champollion had finally time to fully dedicate to the hieroglyphs. The breakthrough came in 1822 and then the milestone in 1824. Searching for comparative materials crucial for his main interest, Champollion went to Italy, where in contrast to his complicated situation in France, he was warmly welcomed. In Livorno he met *Ippolito Rosellini* – his follower, friend, and companion in the journey to Egypt they planned together and finally executed in 1828. Within 18 months of his stay in Egypt, Champollion visited numerous sites from Alexandria, in the Nile Delta, to Nubian Wadi Halfa. In every historical place he saw, he made notes, sketches, plans of monuments, and copies of hieroglyphic inscriptions, often fighting severe attacks of arthritis.

In 1830 Champollion was elected a member of the most prestigious *Académie des Inscriptions et Belles-Lettres*, and the following year, he took up a newly founded chair of Egyptology at *Collège de France*, becoming the first professor of the subject in the history. Unfortunately, he was only able to give a few lectures before he died after a stroke in Paris in 1832.

In 1986, the town of Figeac commemorated its famous fellow countryman by opening the Museum of Champollion.

Major Accomplishments

Champollion is the best known from cracking the code of Egyptian hieroglyphs. It was the task that consumed most of his time and energy with the crucial period concentrated between 1821 and 1828. During his work, Champollion came through various excluding ideas, such as the conviction that Egyptian signs were of purely alphabetical character and belief in relation of Chinese and Egyptian writings; for a long time, he accepted the opinion of classic writers that hieroglyphs have only symbolic meaning, to finally state that the system is not homogenous and had to be complemented by signs of additional character.

The starting point of this long process was the famous Rosetta Stone, discovered in 1799 and soon identified as covered with a text of Ptolemaic

Champollion, Jean-François, Fig. 1 Portrait of Champollion by Léon Cogniet, 1831, presently at Louvre, INV 3294, public domain

Champollion, Jean-François, Fig. 2 Plate IV from *Lettre à M. Dacier* (Champollion 1822) with the famous hieroglyphic alphabet

period decree written in three versions: hieroglyphic, demotic, and Greek. The text mentions two royal names: Ptolemaios and Berenice that were written in a ring, known as cartouche. Champollion accepted that in the special case of foreign names, hieroglyphs were used phonetically, and it was the assumption that formed the base for the famous hieroglyphic alphabet (Champollion 1822). Soon, after decoding further royal names of Egyptian origin, Champollion stated that there had to be a general phonetic component in the hieroglyphic script, to finally note that the writing system was based on a group of ca. 20 phonetic values, each represented by a few sings, a couple of semiphonetic sings, and hundreds of figurative and symbolic ones. This observation was presented in his *Précis du système* (Champollion 1824), republished with major corrections in 1828.

Between 1814 and 1819, a British scholar, Thomas Young, also focused his attention on the inscription from the Rosetta Stone. Although he did not solve the Egyptian riddle, he made some crucial observations on the character of the ancient Egyptian script, in some parts analogous to those published in 1822 by Champollion. There is still an open discussion on the priority of discoveries in the field, which may never be satisfactory closed. However, it seems that Champollion could indeed have been inspired by Young's article published in *Encyclopedia Britannica*, but his later work that actually cracked the Egyptian code was fully original and based on his own methodology.

Apart from sheer decipherment, Champollion was also vividly interested in the ancient Egyptian language. Even at his deathbed, he continued work on grammar and dictionary, which were then published (Champollion 1836, 1841–1843), edited by his devoted brother. The fluency in language and interest in culture (Champollion 1823–1825) put the basis for a new field of knowledge, which is Egyptology. Equally important are also tones of notes and drawings made in Egypt (Champollion 1835–1845), which enlarged the catalogue of original Egyptian works of art crucial for further analyses of the culture but also are the only preserved documentation of many monuments that did not survive our times.

When in 1826 Champollion was nominated a curator in the Louvre, he used his Italian contacts to bring the magnificent collection of Henry Salt to Paris. His ideas and expertise formed one of the world's largest collections of Egyptian art and still – in a way – influence the contact of our culture with the ancient one (Figs. 1 and 2).

Chan: A Tropical Rain Forest Site in Belize

Cynthia Robin
Department of Anthropology, Northwestern University, Evanston, IL, USA

Introduction

Nestled in Belize's lush tropical rain forest, the Chan site was long known to local farmers who still farm the area around the archaeological site. The area was noted by archaeologists in 1994 who were working on a regional settlement survey. The Chan project, a collaborative, international, multidisciplinary research project, began in 2002, bringing together a team of over 120 foreign and local archaeologists, botanists, geologists, geographers, chemists, computer scientists, artists, students, workers, volunteers, and local community residents from Belize, the USA, England, Canada, and China (Robin 2012).

Key Issues/Current Debates/Future Directions/Examples

Chan was occupied by a farming community with a 2000-year history (c. 800 BCE–CE 1200) spanning the major chronological periods of ancient Maya society: the Preclassic, Classic, and Postclassic

periods. Unremarkable in terms of community size or architectural elaboration, Chan nonetheless flourished while the fortunes of nearby major Maya civic centers waxed and waned. Research at Chan was aimed at investigating the everyday lives of Maya farmers and the impact farmers had on Maya society. Given that 2000 years is a long period of time, what did Chan's residents do to facilitate the longevity of their community?

To address these questions, a three-staged research design was developed for the Chan project. Stage 1 involved a full coverage rain forest survey that utilized *Total Station* mapping and a *Geographical Information System* to digitally map the 3.2 km^2 area of the community and record the 274 households and 1223 agricultural terraces that surround Chan's community center (Fig. 1). In Stage 2, extensive *coring* (using a post-hole digger) and full scale *area excavations* were conducted at all buildings in Chan's community center, along with a 10% sample of households (26 households) and associated outdoor activity and work spaces that represent the temporal, socioeconomic, and vocational variability within the community (Fig. 2). Excavation in this terrain involves careful clearance of vegetation and roots to reveal the archaeological features without damaging the stone structures or the trees. Stage 3 research, which was conducted in the field in conjunction with stage 1 and 2 research to facilitate research collaboration, involved the analysis of roughly half a million objects of everyday life, one of the largest archaeological samples from a Maya farming community, and additionally incorporated scientific techniques of soil chemistry, paleoethnobotany, human bone, animal bone, obsidian sourcing, radiocarbon dating, and micro-artifact studies.

The structures and assemblages were classified and analyzed to produce a dated sequence of material practice at Chan over the two millennia. The terraced agricultural landscape was constructed by cooperating farming families, and the agricultural system developed and expanded through time. It avoided soil erosion and maximized water retention, incorporating complex small-scale irrigation and water storage systems. A forest management strategy maintained a diverse mature, closed-canopy, tropical forest even as the population expanded during the Classic period (BCE 250–900), and farmers had a growing need for fuel, construction material, and agricultural land. Extremes of wealth and power were avoided within the community, as all residents from the humblest farmer to the community leaders had access to a similar range of exotic items and lived in perishable houses with similar

Chan: A Tropical Rain Forest Site in Belize, Fig. 1 Undergraduate students Alex Miller, Shelley Khan, and Yasmine Baktash (left to right) set up a Topcon GTS 605 laser theodolite to digitally map Chan's settlement. (Photograph by James Meierhoff)

Chan: A Tropical Rain Forest Site in Belize, Fig. 2 Archaeological illustrators Merle Alfaro (seated) and Nasario Puc (standing) illustrate a terminal deposit of broken ceramic on Chan's central ritual structure. Excavators Lazaro Martinez, Everaldo Chi, and Ismael Chan (left to right) are in the background. (Photograph by James Meierhoff)

outward appearances. Ritual and political practices within the community incorporated all residents and focused on the community as a whole rather than individual community leaders.

This long-term stability contrasts with that of the opulent Maya civic centers with their towering temple pyramids that form the usual focus of Maya archaeological research. Avoidance of extremes of wealth and power, more equitable distribution of goods, consistency in health, and communal focus of ritual and politics are some of the socially effective strategies established by Chan residents. The sustainable forest management practiced at Chan is distinct from the more extractive practices seen at the larger Maya civic centers where royals culled the mature forest across the Classic period. The consistent presence of a low degree of biological stress in the Chan skeletal population indicates persistent good health at Chan. This contrasts with that seen at larger Maya civic centers where residents' health declined by the end of the Classic period as indicated by increasing degrees of biological stress.

These studies, drawn from systematic fieldwork at a seemingly unremarkable place such as Chan, thus offer important lessons about human societies, particularly in the matter of social and economic sustainability.

Chang, K.C.

Alice Yu Cheng
University of Oxford, Oxford, UK

Basic Biographical Information

Kwang-chih Chang (1931–2001), or K.C. Chang, was born in Beijing in 1931 and moved with his

family to Taiwan in 1946. He attended the National Taiwan University in 1950 and was among the first class of undergraduates in the Department of Archaeology and Anthropology. He was taught by Li Chi [Li Ji] and other key archaeologists such as Dong Zuobin [Tung Tso-pin 董作賓], Gao Quxun [Kao Chu-hsun 高去寻], and Shi Zhangru [Shih Chang-ju 石璋如]. From 1955 to 1960, Chang pursued a doctorate in anthropology at Harvard University, studying under Hallam L. Movius Jr., Clyde Kluckohn, Lauriston Ward, and Gordon R. Willey. After graduation, he taught at Harvard (1960–1961) and Yale (1961–1977) and returned to Harvard again from 1977 until his retirement in 1996. At Harvard, he was named the John E. Hudson Professor of Archaeology in 1984 and served also as curator at the Peabody Museum.

Though teaching in the USA, Chang remained active in developing the archaeological field in Taiwan. In 1961, he initiated projects on the prehistory of Taiwan and conducted excavations in 1964–1965 at the sites of Tapenkeng 大坌坑in Taipei 台北and Fengpitou 凤鼻头 in Kaohsiung 高雄. In 1972–1974, with the support from the National Science Council (Taipei), the National Science Foundation, and Yale University, he led the project "Anthropological and Environmental Investigations in the Choshui and Tatu River Valleys of Central Taiwan," an interdisciplinary research dedicated to investigate changes in the cultural ecology of the region. In 1986, he began the "Field Research Project on Taiwan History" at Academia Sinica, facilitating the collaboration between scholars from multiple fields. Such a project eventually led to the establishment of the Institute of Taiwan History at Academia Sinica in 1993. In 1994, Chang became the vice president of the Academia Sinica.

Chang, on the other hand, was devoted to promoting exchanges between the West and China. In 1975, he visited China as a member of the American Paleoanthropological Delegation, opening door to the significant intellectual exchanges and conferences in the next decades. In 1984, he gave six important lectures at Peking University and a lecture series in Shandong University, Jilin University, and Xiamen University. Working on his interdisciplinary project "Investigations into Early Shang Civilization," Chang collaborated with scholars from the Institute of Archaeology of the Chinese Academy of Social Sciences in Beijing. In the 1990s, he was able to conduct surveys and excavations at the site believed to be the Great City Shang near present-day Shangqiu商丘, Henan.

Major Accomplishments

K.C. Chang contributed profoundly to the development of archaeological theory, particularly that in the USA. Active in the theoretical movement of his time, he advocated the social aspects of the artifacts and the need to understand processes of cultural change. Moving beyond analyzing the artifacts as closed entities, Chang introduced new methodologies and terminologies to classify artifacts for the purpose of reflecting social relations and cultural activities. For example, in *Rethinking Archaeology* (1967), he identifies and critiques the basic issues in archaeology, such as the role of artifacts in cultural and collective transformation and the analysis and articulation of data in determining regular social patterns.

Focusing on the Shang period, Chang deepened the understanding of the livelihood, social structure, and material culture of the Shang communities. In *Shang Civilization* (1980), he pulls together the previous and newly emerged archaeological evidences such as bronzes and oracle bones, as well as revisits transmitted texts. Chang draws important conclusions on larger and broader subjects concerning the Shang communities, for example, the political organization of the Shang regime, its symbols of authority and rule, the importance and function of lineage, etc. He also considers the possibility of establishing an absolute chronology of the Shang dynasty. In *Art, Myth, and Ritual: The Path to Political Authority in Ancient China* (1983), Chang focuses on major archaeological sources and opens up new directions to understand ancient China, including the Shang regime. One of the main themes he explores is the presence of shamanism and its role in consolidating religious and political authority.

Chang's interdisciplinary approaches and focus on international collaboration helped shape the course of modern Chinese archaeology, both in the USA and China. He initiated English translations of the Chinese archaeological reports and abstracts on pre-Imperial excavations. In *The archaeology of Ancient China*, first published in 1963 and subsequently in 1968, 1977, and 1986 with substantial revisions and addition of new data, Chang provides a detailed account of a wealth of archaeological evidences from China. He also interprets the artifacts within the framework of anthropological approaches. On the other hand, besides giving lectures in China, he also published frequent brief papers comparing and contemplating on issues in Chinese and Western archaeology. As many of his publications were made available in Chinese, he brought in new approaches for the Chinese-speaking audience to interpret archaeological data.

Chang's extensive research and fieldwork on Taiwan prehistory also advanced the field of modern archaeology in Taiwan. He published his excavation findings in *Fengpitou, Tapenkeng, and the Prehistory of Taiwan* (1969), the first book on Taiwan prehistory. His anthropological and environmental fieldwork in the 1970s provided the training for next generations of archaeologists and anthropologists in Taiwan and created a model for subsequent academic programs. As vice president of the Academic Sinica, he promoted international and multidisciplinary collaborations.

Basic Biographical Information

Over the course of his 40-year career, Kwang-chih (K.C.) Chang (1931–2001) (Fig. 1) integrated traditional Chinese historiography with American anthropological archaeology to help fundamentally transform our understanding of cultural developments in early China and Southeast Asia. Born in Beijing in 1931, K. C. and his family returned to their native Taiwan in 1946. As an undergraduate from 1950 to 1954 in the newly established Department of Archaeology and Anthropology at National Taiwan University (NTU), K. C. studied under many of the most eminent scholars of early East Asia, including archaeologists Li Chi (1896–1979) and Shih Chang-ju (1902–2004), ethnographer Ling Shun-sheng (1902–1981), and historical linguist Tung T'ung-ho (1911–1963).

Following the advice of his mentor Li Chi (who had earned his Ph.D. in Anthropology at Harvard in 1923), K. C. undertook graduate studies in that department from 1955 to 1960, working closely with key Harvard faculty who would

Chang, Kwang-chih, Fig. 1 Kwang-chih Chang

further shape his career, including cultural anthropologists Evon Vogt and Douglas Oliver, archaeologists John Otis Brew and Gordon Willey, and ethnologist Clyde Kluckhohn. Chang's primary faculty advisor was Hallam Movius Jr., with whom he worked at the Upper Paleolithic site of Abri Pataud near Les Eyzies, France, instilling in Chang a lifelong interest in Paleolithic foundations.

Hired as a lecturer in anthropology at Harvard during 1960–1961, K. C. was a quickly rising star in the field, invited to participate with much more senior scholars at the seminal 1960 Wenner-Gren Foundation symposium *From 15,000 BC to the thresholds of civilizations* at Burg Wartenstein, Austria. He joined the Anthropology faculty at Yale from 1961 to 1977, where he taught a range of courses on Chinese, East Asian, and Southeast Asian archaeology, and also served as departmental chair from 1970 to 1973. His enthusiasm for Chinese archaeology was enhanced by the steady flow of new discoveries from China slowly opening up after a decade of seclusion during the Cultural Revolution, sites that K. C. saw firsthand as a member of the American Paleoanthropology Delegation to China in 1975, his first trip there since leaving as a young boy three decades earlier.

In 1977, after considerable deliberation, Chang left Yale to return to his beloved Harvard as professor of anthropology and curator of Asiatic archaeology at the Peabody Museum. He was appointed as the John E. Hudson Professor of Archaeology in 1984 and taught courses tailored to his specific archaeological interests, including Chinese archaeology and Shang civilization, innovative courses in the college's evolving core curriculum, and, his favorite, the Harvard Freshman Seminars. He retired in June 1996 due to the debilitating effects of Parkinson's disease. "I consider it the highest honor," Chang would write to Harvard's president, "for any academic to retire as a Harvard professor – at least in the hearts of some diehard Harvard partisans and I confess to be one of them." K. C. Chang died in Boston on January 3, 2001.

Major Accomplishments

Chang's archaeological career, reflected in his more than 350 publications that cover an exceptionally broad range of topics, spanned a particularly critical time in the development of the field both in the West and in East Asia. His undergraduate and graduate teachers very much influenced his work on archaeological theory. In particular, Gordon Willey's research on settlement patterns in Peru's Viru Valley and discussion of concepts such as "traditions" and "horizons" helped to shape Chang's 1960 Harvard doctoral dissertation that explored settlement patterns in Neolithic and Bronze Age China. In his subsequent edited volume (Chang 1968), the importance of settlement data in understanding human organization was examined through an array of enlightening case studies and theoretical excursions. Chang quickly became an important player in the often contentious debate about the "New Archaeology" that dominated Western scholarship during the turbulent 1960s and early 1970s, and he brought these debates to bear on the archaeological data increasingly coming to light from China. His book *Rethinking Archaeology* (Chang 1967a) reflected his desire to introduce concepts and terminology that would allow material remains to be more

culturally meaningful. That same year, his major essay on the importance of ethnographic analogy in archaeology (Chang 1967b) elicited strong disagreements from Lewis Binford and others. In these works, Chang also stressed the importance of recognizing that archaeology was a tool that could be transformed to meet the needs of society, an awareness that would serve him well in understanding the changing role of archaeology in an evolving post-revolution China.

Chang sought to bring interdisciplinary archaeology to Taiwan, leading a collaborative Yale-NTU field project from 1964 to 1965 at the prehistoric sites of Tapenkeng and Fengpitou that examined early horticulture within a framework of comprehensive environmental reconstruction (Chang 1969). This was followed in 1972–1974 by his intensive study of subsistence, settlement patterns, and human-ecosystem interaction in central Taiwan, a project marked both by its broad interdisciplinary nature and its long-term impact as a training ground for a new generation of Taiwan archaeologists. He was a key consultant to the establishment of Taiwan's National Museum of Prehistory and also pressed for support for the study of Taiwan history and historical archaeology.

K. C. Chang's name is synonymous in the West with Chinese archaeology. His four editions of *The Archaeology of Ancient China* (e.g., Chang 1986) brought to Western readers an authoritative presentation and interpretation of the steadily increasing archaeological data coming out of China, each edition thoroughly updated to reflect the latest finds. His comprehensive work on China's early Bronze Age (17th–11th C. BCE), no doubt inspired by his teachers who represented the very first generation of Shang archaeologists in the 1930s, carefully integrated Western anthropological theory with a mastery of field data and early Chinese textual sources (Chang 1980, 1983).

International conferences on Chinese archaeology during the late 1970s and 1980s, many of them organized by Chang, helped to open up Chinese archaeology to foreign scholars and students and to expose Chinese scholars to world archaeological method and theory. When China's laws were changed in the early 1990s to allow Sino-foreign collaborative field projects, Chang was among the first to be invited, and the Peabody Museum-Chinese Institute of Archaeology project *Investigations into Early Shang Civilization*, based in the North China Plain at Shangqiu, Henan province, brought together Chinese and American scholars in an extended effort to locate and understand the predynastic phase of Shang culture (Murowchick and Cohen 2001). This helped to foster a collaborative atmosphere that today is represented by an array of international projects across China.

Recognition of Chang's accomplished career included his research appointments at Academia Sinica (Taipei), election to the US National Academy of Sciences (1979), American Academy of Arts and Sciences (1980), and the Society of Antiquaries of London. The Association of Asian Studies honored his "Distinguished Contributions to Asian Studies" (1986), and he won the University of Pennsylvania's Lucy Wharton Drexel Medal (1987), among many other honors. He was a transformative figure in the field of East Asian archaeology, a bridge between East and West, and a catalyst for the international collaborations that thrive today.

Charcoal: Preservation and Conservation

Caroline Fernandes Caromano[1] and Leandro Matthews Cascon[2]
[1]Museu de Arqueologia e Etnologia, Universidade de São Paulo, São Paulo, Brazil
[2]Faculteit Archeologie, Universiteit Leiden, Leiden, The Netherlands

Introduction

Charcoal (carbonized wood) is of great importance in archaeology. In archaeological sites, charcoal is interpreted as evidence of the use of fire by past populations for various purposes and is a source for the absolute dating of contexts, for conducting paleoenvironmental reconstructions, and for discussing past relationships between human groups and their environment. In order to reach the great potential existent in the study of archaeological charcoal, it is necessary to take into account the processes which affect preservation up to their moment of collecting, as well as the methods necessary for their conservation.

Definition

Archaeological charcoal preservation and archaeological charcoal conservation are somewhat distinct, although correlated, terms. Charcoal preservation refers to aspects both before and after charcoal is collected from an archaeological context, encompassing the moment it was first produced in the past, the natural and cultural processes it underwent through time, up to present day when it is collected and studied. Charcoal conservation, on the other hand, refers to efforts taken during and after charcoal is collected, such as the proper maintenance of its physical integrity during excavation, transportation, analysis, and storage.

Key Issues/Current Debates/Future Directions/Examples

Archaeological charcoal can be studied in a variety of ways. One way in which charcoal is regularly used in archaeology is as evidence of past human activity, such as in pre-modern human sites where charcoal remains are frequently interpreted as evidence of the past use of fire by hominins.

After the discovery of radiocarbon dating, researchers became even more aware of charcoal found in archaeological contexts (Heizer 1963). Charcoal is frequently used as material for absolute dating of archaeological contexts, especially in the time spanning the last 50,000 years.

Archaeological charcoal may furnish even more information about the past if certain methods and techniques are applied to its study. The quantification of charcoal fragments in archaeological units and profiles, for example, can furnish information on past human activities such as the clearing of areas through time for the establishment of settlements and the preparing of fields and gardens for cultivation.

Other types of information may also be gathered if an effort is taken in identifying which plants did charcoal fragments originate from. Through microscopic observation and comparison with reference collections from modern plants, it is possible to conduct charcoal analysis by taxonomically identifying charcoal fragments. By knowing which plants were used in the past, one can interpret what past environments may have looked like, the relationships that past human groups had with their surrounding environment, and for what sorts of purpose different plants were used, not only for everyday use as firewood but for other specific purposes, from the production of artifacts to mortuary practices.

It is important to take into account the fact that archaeological charcoal is a fraction of the total amount of wood that was used in past contexts. In order to better understand the relevance of archaeological charcoal in furnishing information on the past, it is imperative to try to understand the processes which, in one hand, allow charcoal preservation until present day and, on the other hand, destroy or alter charcoal material, thereby furnishing us with a partial view of the past.

The burning of wooden material results in the production of ashes, when there is a total combustion of the organic matter, or of charcoal, when there is incomplete combustion of the material (Huisman et al. 2012). If charcoal is produced by burning with a limited supply of air, it is considered the result of "charring," while if it is produced by burning without oxygen, it is considered the result of "carbonization" (Braadbaart and Poole 2008; Théry-Parisot et al. 2010). The term "charcoalification" may be used to define the processes which result in the production of charcoal, regardless if the process was by charring or by carbonization (Braadbaart and Poole 2008). Charcoal may be a by-product of an activity (such as resultant from an extinct hearth), or it may be the desired end in itself (such as charcoal intentionally produced in charcoal kilns).

Archaeological charcoal assemblages are the result of human practices and natural phenomena. Wood collecting, management of hearth structures including wood arrangement, combustion characteristics such as temperature of burning and oxygenation, and wood features such as anatomy, density, and chemical composition are all factors which influence charcoal fragmentation and loss of mass material, which in turn affect charcoal preservation. After production and use, charcoal fragments are subject to further events through time, such as physical impact by humans and other animals and environmental factors such as wind, rainfall, and changes in temperature, processes which result in horizontal and vertical dispersion as well as fragmentation and disappearance of charcoal material (Théry-Parisot et al. 2010).

Charcoalified material is less subject to physical and chemical decomposition in soils, being the most common mode of survival of plant material in archaeological sites (Braadbaart and Poole 2008). It has been traditionally stated that through the process of burning, water and fugitive compounds are expelled from wooden material and the remaining structure would be a chemically stable mineral state not subject to organic decomposition (Dincauze 2000:334). Recent research has shown, however, that charcoal is not composed of pure carbon but in fact of aromatic compounds (benzenoids), making them unstable in alkaline conditions (Braadbaart and Poole 2008; Huisman et al. 2012).

The identification of various postdepositional processes affecting charcoal preservation, alongside recent demonstration that charcoal is not as stable as previously thought, has resulted in the increase concern that charcoal absence in certain archaeological contexts might, in fact, be due to processes of fragmentation and destruction of previously existent charcoal fragments. The absence of charcoal in many contexts might, for example,

be the result of charcoal disintegration in alkaline soils (Braadbaart et al. 2009; Théry-Parisot et al. 2010). What's more, wood and plant ashes are alkaline, meaning that, in many contexts, charcoal fragments buried alongside ashes (as in fireplaces) might have disintegrated (Huisman et al. 2012). Charcoal taphonomy is an important issue to field archaeology (Scott and Damblon 2010).

Despite its shortcomings, charcoalification may be considered as a very fortunate event to the study of the past. A great number of studies have shown that, although charcoalification produces some changes in wood structure, most anatomical characteristics remain, including those of microstructural elements so important for taxonomic determination (Rossen and Olson 1985; Braadbaart and Poole 2008; Théry-Parisot et al. 2010). In fact, even structures produced in wood due to attack by microorganisms may be preserved after burning (Moskal-del Hoyo et al. 2010). Although charcoal is subject to various processes which affect their preservation, it is still identifiable as well as datable, proving itself a valuable study material for archaeology.

An important factor in charcoal preservation consists in the methods and techniques chosen for recovery during excavation. Frequent scraping by trowel or other instruments has a destructive effect on charcoal fragments. Charcoal samples should preferentially be collected by removal of soil matrixes in small blocks, respecting the limits of archaeological layers and structures (Scheel-Ybert et al. 2006).

Collecting of charcoal concentrations in situ and dry-screening, wet-screening, and flotation of soil samples are the main methods used by archaeologists in the field, and each of these methods has its own advantages and disadvantages, as well as consequences on the physical preservation of charcoal. If done without caution and with too much force, dry-screening and wet-screening can destroy charcoal fragments.

Flotation, which consists in the separation of material from the sediment matrix by immersion in water or a chemical agent, is an important technique for the recovery of botanical macroremains, but it also affects preservation (Arranz-Otaegui 2016). Flotation results in charcoal fragmentation and loss due to mechanical stress of two types, physical impact with the water and later internal stress as charcoal fragments dry out (Arista 2013). Flotation can cause a possible underrepresentation of charcoal from plants subject to rotting of fungi and termite attack, as well as a possible overrepresentation of charcoal which became vitrified during burning (Arranz-Otaegui 2016). In order to maintain charcoal damage to a minimum, soil samples must be dried before flotation and treated gently, not packed tightly into bags or subject to heavy weights, being preferable to store them in sturdy plastic containers before flotation (Pearsall 2000:13–76). After flotation, charcoal fragments must be dried in a shaded location before being handled due to their great fragility when wet (Scheel-Ybert et al. 2006).

All archaeological samples containing botanical material, be them soil samples for future screening or flotation procedures or charcoal fragments themselves, must be properly identified at the site in adequate containers so as to be handled with care during transportation and storage, maximizing their preservation and conservation.

Conservation issues also possess great importance in certain contexts where charcoalified structures and artifacts are present, requiring adequate techniques for the maintenance of their physical integrity. Despite this, the conservation of charcoalified wood recovered from dry or waterlogged contexts is not a frequent practice, and few studies have been published on the subject (Caple and Murray 1994; Cobb 2005; Pizzo et al. 2011; Arista 2013). The techniques applied to the conservation of charcoal found in waterlogged conditions are not directly applicable to material found in dry conditions (Pizzo et al. 2011), the same being true for techniques traditionally used for non-burnt wooden artifacts (Caple and Murray 1994).

An important aspect of research on charcoal conservation refers to the comparison of different consolidants for maintaining their structure, being already a subject matter over seven decades ago regarding charcoal conservation for dendrochronology (Hall 1946).

Current studies on conservation of waterlogged charcoalified material with the application of polyethylene glycol demonstrated that, although at

times visual characteristics were preserved, the methods and material used were not successful in sufficiently strengthening charcoal structures (Triantafyllou et al. 2010) or large pieces of charcoalified artifacts (Caple and Murray 1994). Regarding the conservation of dry charcoalified material, tests have demonstrated differences between consolidants. Comparative tests of thermoplastic resins have been successfully conducted for charred wood structures (Stromberg 1999; apud Arista 2013). Other tests with experimentally charred wood have, however, pointed to possible risks to the structural integrity of charcoal when using thermoplastic resins (Cobb 2005). Acceptable results to charcoal conservation have also been demonstrated when water-soluble resins were applied on a partially charred artifact (Pizzo et al. 2011).

Experiments on charcoal consolidants have also been conducted on dry charcoalified material recovered using flotation techniques. Consolidation of archaeological charcoal would preferably occur before flotation and its effects on charcoal preservation, but since that is not possible, efforts have been made to understand if consolidation after flotation can still help strengthen charcoal for transporting as well as preserve anatomical structures for wood identification (Arista 2013). In general, regarding charcoal conservation researchers advocate the need for further experimentation in order to better define consolidants and techniques adequate for the conservation of both waterlogged and dry charcoalified archaeological vestiges.

Another aspect related to charcoal preservation and conservation refers to its application in absolute dating. The process of dating charcoal includes steps in which contaminants are removed by a method known as the acid-base-acid pretreatment, a method which has shown to result in structural and chemical changes to charcoal (Rebollo et al. 2008).

Charcoal from archaeological contexts is material proof of past intentional or unintentional fire events and provides archaeological information regarding multiple dimensions of the human and environmental past. Attention to charcoal preservation and conservation issues is, therefore, imperative in order to access all the potential information that might be extracted from them.

Charlton, Thomas H.

Patricia Fournier
Posgrado en Arqueología, Escuela Nacional de Antropología e Historia, México, DF, Mexico

Basic Biographical Information

Thomas H. Charlton was born in Scarborough, Ontario, Canada, on August 17, 1938. He obtained a doctorate in Anthropology from Tulane University in 1966 with a dissertation in the vanguard of studies dealing with archaeological settlement patterns in central Mexico. His academic career as a faculty member in the Department of Anthropology at the University of Iowa began in 1967, where he became a senior archaeologist as a Mesoamericanist and New World specialist.

Charlton's research included studies of the Historical Archaeology of Plum Grove in Iowa City, the nineteenth century home of the first territorial governor of Iowa, a site included in the US National Register of Historic Places. At the site, he undertook collaborative investigations beginning in 1974 and directed an annual summer field school from 1995 to 2010. For almost four decades he was active in teaching and research and served in multiple academic activities in the anthropology department of the University of Iowa. He trained undergraduate and graduate students in the USA and in Mexico with research in the fields of Mesoamerican and Historical Archaeology until his untimely demise in June 2, 2010.

Charlton's investigations were characterized by careful fieldwork in surveys and excavations, thoroughness in laboratory analyses, and detailed archival research. He was a man of three nations: born in Canada, residing in the USA, and with deep connections with Mexico, its history and its people. He was an outstanding, prolific, and generous scholar passionate about archaeology, ethnohistorical sources and ceramics, who had a soft spot for cats.

Major Accomplishments

Thomas H. Charlton was the first scholar whose research in central Mexico explicitly applied scientific approaches and historical anthropological insights to the understanding of cultural continuities and change after the Spanish conquest in CE 1521. Since the 1960s his main interest was in understanding the development of pre-Columbian social complexity, mostly in central Mesoamerica, and particularly in the Basin of Mexico as a symbiotic region. He focused his research on the Classic period of urban and rural contrasts in the Teotihuacan Valley and the Late Post-Classic

city-state of Otumba (e.g., Charlton 1972, 1973, 1986). He noted that in Mexico archaeologists traditionally had failed to venture into post-conquest studies (Charlton 1972: 107); therefore, Charlton advocated for a holistic approach to anthropological investigations, integrating ethnographic, ethnohistorical, and archaeological data, generating a combined approach to provide a better understanding of Colonial Mesoamerica (Charlton 1969: 286). He emphasized that analogy is a major approach by which ethnographic and ethnohistorical data contribute to an understanding of the past, constituting a zone of transfer and contact between disciplines. Moreover, he set the bases for the use of historical records to interpret archaeological data as a mode of direct historical analogy, and thus to strengthen inferences using relevant empirical data (Charlton 1981: 130, 154, 158) (Fig. 1).

Charlton developed the methodological foundations on which to conduct major studies of the historical archaeology of cultural transformations and dynamics during the Colonial and Republican periods (CE 1521–1910) in Mexico (Charlton 1986). His insights were based on hard empirical data, employing an elaborated culture history model to comprehend acculturative processes and cultural change from the Early Colonial period (CE 1521–1620) onto the twentieth century (e.g., Charlton 1975; Charlton and Fournier 1993: 214; Charlton et al. 2005).

Charlton, Thomas H., Fig. 1 Thomas H. Charlton in 1970

His publications show explicitly how descriptive information may be framed to infer major social processes in historical archaeology, including acculturation, pre-Columbian to Colonial demography, changes in settlement patterns and land use, continuities and deterioration of indigenous ceramic traditions and styles after the Spanish conquest, craft specialization, transformations in trade and exchange patterns from the Post-Classic to the Colonial period, consumption trends, the development of ranchos and haciendas in rural areas, and other important topics.

Charlton was remarkably influential in promoting post-conquest archaeology in Mexico as legitimate and noteworthy anthropological research. His methodology is applicable to almost any area for which there exists documentation (Charlton 1969: 292) and even for the understanding of cultural processes in regions or sites where historical records are scant or nonexistent but are suitable for broader comparisons with better documented areas.

His book, *Post-conquest Developments in the Teotihuacan Valley* (1973), constitutes a seminal and major contribution to the historical archaeology of the Basin of Mexico. Many American scholars specializing in historical archaeology have drawn on his perspectives and work. Moreover, since Charlton undertook collaborative research with several Mexican archaeologists, they and their students are and will continue to keep his methodological legacy alive to contribute to the field of historical archaeology.

Charoenwongsa, Pisit

Thanik Lertcharnrit
Department of Archaeology, Silpakorn University, Bangkok, Thailand

Basic Biographical Information

Pisit Charoenwongsa is a prominent Thai professional archaeologist and a pioneer scholar in cultural resource management who has been active in these fields for a number of decades. He was born in 1941 and grew up in the eastern province of Chachoengsao, obtaining his B.A. in archaeology from Silpakorn University in 1964. He attended the nondegree postgraduate program in archaeology at the University of London in the UK from 1968 to 1971. He went on to pursue his graduate studies at the University of Pennsylvania, USA, where he received an M.S. in anthropology in 1972. In 2000, he was awarded an honorary Ph.D. (Prehistoric Archaeology) from Silpakorn University.

Pisit Charoenwongsa began his career as a full-time lecturer of archaeology in 1967 at the Silpakorn University Faculty of Archaeology, where he taught and conducted research on the prehistory of Thailand and neighboring countries for seven years (1967–1973) before transferring to the Fine Arts Department (FAD) in 1974. He served in the FAD for 16 years (1974–1990). In 1990, Pisit resigned from the FAD to assume a position as senior specialist and later was promoted to serve as director-general of the SEAMEO Regional Center for Archaeology and Fine Arts (SPAFA), an international organization with members from 11 Southeast Asian countries, until his retirement in 2000. In addition, Pisit has served in various capacities in a number of nonprofit, private, and public educational and cultural organizations, and has played a variety of significant roles in the study, development, and preservation of cultural heritage. To name a few, he served as the president of the Indo-Pacific Prehistory Association (1996–2000), executive member of the International Council on Monuments and Sites (ICOMOS), editorial board member for Southeast Asia of the Journal of Conservation and Management of Archaeological Sites, and member of the International Coordinating Committee for Safeguarding and Development of the Historic Site of Angkor. Currently, he serves as chair of the Committee for Preparation of the Thai-Language Encyclopedic Dictionary of Global Archaeology, which is hosted and funded by Thailand's Royal Institute. The dictionary will be the first Thai-language dictionary of world archaeology and will serve as a major reference for teachers, students, archaeologists, and those who are interested in archaeology, history, history of art, and cultural resource management.

Major Accomplishments

Throughout his career as lecturer, archaeologist, academic advisor, writer, administrator, committee member, peer-reviewer, and so on, Pisit Charoenwongsa has contributed tremendously to the better understanding, promotion, development, and preservation of archaeological and cultural resources in Thailand in particular and in Southeast Asia in general. Pisit has been actively engaged at

both national and international level in the research, study, protection, development, and management of cultural resources projects. He has been invited to share his expertise and insight on the subject throughout Thailand and other countries.

Charter for the Conservation of Historic Towns and Urban Areas (Washington 1987)

Sofia Avgerinou Kolonias
COMOS-CIVVIH, National Technical University of Athens, Athens, Greece

C

Brief Definition of the Topic

Introduction

In 1964, the Second International Congress of Architects and Technicians of Historical Monuments, organized in Venice under the auspices of UNESCO, adopted 13 resolutions, the International Charter for the Conservation and Restoration of Monuments and Sites, better known as the Venice Charter, among them. The second resolution was the act establishing an international non-governmental organization for the protection of monuments and sites, the International Council on Monuments and Sites (ICOMOS). Lastly, the eighth resolution was a request for the protection and revival of historical centers. This entry has constituted the starting point of the efforts made by ICOMOS for the adoption of a policy for the protection and restructuring of historical towns.

ICOMOS elaborated the views expressed in the Charter in the 20 years' period following the Venice Congress, according to the developments in the debate and practice for the protection and conservation of monuments and sites. After the first papers were collected by CIVVIH (*Comité International des Villes et Villages Historiques* [International Committee on Historic Towns and Villages]) following a debate with ICOMOS National and Scientific Committees, the *Charter for the Conservation of Historic Towns* was adopted in 1987 by the General Assembly of ICOMOS in Washington, DC. The Charter has remained loyal to the objectives of the *"Recommendation Concerning the Safeguarding and Contemporary Role of Historic Areas"*(*Warsaw – Nairobi, 1976) of UNESCO*. However, without being a sole repetition of the Declaration, its Articles contain both its philosophical view and its practical objectives.

Definition and Scope

This Charter is intended for specialists (especially architects, urban planners, and spatial planning engineers, geographers and ecologists, and infrastructure engineers) and those involved in planning in general or making decisions regarding the urban development process. The Charter makes an appeal to the younger generations and to the wider society to mobilize themselves to protect historical towns. The Charter supports the development approach to conservation and restoration by adopting, as a basic principle, that conservation should be integrally connected to economic and social development. Moreover, its notion of historical town conservation comprises all necessary measures, not only for their protection but also for their development and adaptation to modern life.

The Charter consists of three parts: (1) preamble and definitions, (2) principles and objectives, and (3) methods and instruments.

The first part lays down the scope of the Charter, which includes historical settlements and towns (both small and large); historical centers and districts, as well as their greater environment (both natural and built); and the risks of degradation, de-structuring, and destruction thereof due to the modern urban development.

The second part lays down that the effective preservation of historical towns and districts must be related to economic and social development policy and be taken into account by the urban and spatial plans implementing it within the space. The primordial value of the town's historical character must be preserved. In fact, disciplined and careful intervention is recommended, as is the participation of residents.

The third part underlines the need for plans of the conservation of historic towns and districts to be preceded by multidisciplinary studies. A conservation plan must thoroughly break down the data available (archaeological, historical, architectural, technical, social, and economic) and suggest directions and actions at the legislative, administrative, and financial levels with the consent and participation of the residents.

Current Interpretations

Today, disciplinary views have converged as to acknowledge that the town is a global phenomenon created through historic and material processes and that it evolves to the extent that human societies evolve as well. To that end, it has been pursued that the Charter constitutes a framework document that is specified and adapted to the particularities of the urban phenomenon in each geographical area.

Charter for the Protection and Management of the Archaeological Heritage (1990)

Ricardo J. Elia
Department of Archaeology, Boston University, Boston, MA, USA

Brief Definition of the Topic

In the field of heritage management, international charters are important documents that establish

guidelines and principles for best practices. Although essentially hortatory, in the sense that they lack the force of law embodied in the international cultural heritage conventions, heritage charters are an important source of guidance for governments, institutions, preservation practitioners, and the general public. The best-known and most influential example of a heritage charter is the 1966 Venice Charter (*International Charter for the Conservation and Restoration of Monuments and Sites*), drafted and adopted by ICOMOS, the International Council on Monuments and Sites.

ICOMOS is an international, nongovernmental organization dedicated to the preservation of the world's cultural heritage. Organized into national committees (there are currently 95) with numerous specialized scientific subcommittees, to date, ICOMOS has adopted 14 charters relating to heritage preservation, including archaeology, historic gardens and landscapes, historic towns and urban areas, and cultural tourism, to name just a few (ICOMOS n.d.). In 1990, ICOMOS adopted the *Charter for the Protection and Management of the Archaeological Heritage* in response to concerns about increasing threats to archaeological heritage from development, looting, and other activities (Elia 1993). It is the first comprehensive statement to express the need for effective policies relating to archaeological heritage management on the international, national, regional, and local levels. Although some of its provisions seem a bit outdated or lacking today (e.g., the limited role devoted to participation by indigenous and local peoples), the Charter remains an important articulation of the need for advance planning and rational decision-making in the realm of cultural heritage management. A later charter, adopted by ICOMOS in 1996, deals specifically with the challenges of managing underwater cultural heritage (ICOMOS n.d.).

The organization of the 1990 Charter reflects its effort to reach out to diverse interests (Table 1). Following an introduction that defines archaeological heritage very broadly as "all vestiges of human existence" (Article 1), the Charter addresses issues of primary concern to planners (Article 2) and lawmakers (Article 3), professional archaeologists and heritage managers (Articles 4–7), and academics (Article 8) and ends with an appeal for international cooperation (Article 9).

Charter for the Protection and Management of the Archaeological Heritage (1990), Table 1 Structure of the 1990 *Charter for the Protection and Management of the Archaeological Heritage*

Introduction
Article 1. Definition and Introduction
Article 2. Integrated Protection Policies
Article 3. Legislation and Economy
Article 4. Survey
Article 5. Investigation
Article 6. Maintenance and Conservation
Article 7. Presentation, Information, and Reconstruction
Article 8. Professional Qualifications
Article 9. International Cooperation

Recognizing that archaeological heritage is "a fragile and non-renewable resource," Article 2 of the Charter emphasizes the need for archaeological heritage management to be fully integrated into policies for land-use, development, environment, culture, and education, including meaningful involvement of the general public and indigenous peoples. Article 3 terms the protection of archaeological heritage "a moral obligation upon all human beings" and a "collective public responsibility." This responsibility requires protection for the sake of all humanity, not just for national or local interests. Consonant with this perspective, Article 3 calls for legislation to protect archaeological heritage from unauthorized destruction or alteration; to require investigation and documentation in cases where destruction or alteration is permitted; and to provide for proper maintenance, management, and conservation. These provisions are especially relevant for development projects in order to minimize their potential adverse effect on archaeological heritage.

The next two articles of the Charter focus on professional practice. Article 4 stresses the importance of archaeological survey data to help

planners make effective decisions relating to development. Article 5 emphasizes the need for nondestructive techniques and partial excavation in preference to total excavation and, significantly, gives a priority to the excavation of threatened sites over nonthreatened sites. The latter, according to the Charter, may be excavated "in exceptional cases . . . to elucidate research problems or to interpret them to the public." Here, the Charter seems to be urging a move by archaeologists away from their traditional, research-oriented excavations of sites purely for scientific purposes to the perhaps less glamorous, but more urgent, excavations of a diminishing heritage resource base. It certainly reflects a broad shift in many nations away from academic archaeology to public archaeologists engaged in what has been called compliance, or contract, archaeology.

Article 6 states that "the overall objective of archaeological heritage management should be the preservation of monuments and sites in situ, including proper long-term conservation and curation of all related records and collections etc." Post-excavation maintenance and conservation is necessary, as is participation by local and indigenous peoples. In Article 7, the Charter highlights the importance of public access to sites, monuments, and heritage information but urges caution in the use of reconstructions.

In several respects, the *Charter for the Protection and Management of the Archaeological Heritage* envisions a field that is much larger than that of traditional academic or research archaeology. In its engagement with legislation, development, interpretation, and various stakeholders, archaeological heritage management requires different skill sets from what traditional academic archaeology has provided. The last two articles of the Charter address the needs of the developing profession of archaeological heritage management. Article 8 calls for academic training to "take account of the shift in conservation policies from excavation to in situ preservation." Article 9 stresses the importance of international cooperation in developing and exchanging expertise in archaeological heritage management.

More than two decades after the adoption of the ICOMOS *Charter for the Protection and Management of the Archaeological Heritage*, its essential principles remain valid, and the *Charter* remains an important aspirational document. While more and more nations have adopted, at least in principle, the conservation ethic that is embodied in the notion of archaeological heritage management and while greater numbers of archaeologists and other professionals are engaged in its practice than ever before, the need for more effective legislation, policies, and protection remains a pressing issue in most parts of the world today.

Charter for the Protection and Management of the Underwater Cultural Heritage (1996)

Elizabeth S. Greene
Department of Classics, Brock University, St. Catharines, ON, Canada

Introduction

At its 11th General Assembly held in Sofia in October 1996, the International Council on Monuments and Sites (ICOMOS) ratified its Charter

on the Protection and Management of the Underwater Cultural Heritage (see http://www.international.icomos.org/under_e.htm). The 1996 Charter was developed by the International Committee on the Underwater Cultural Heritage (ICUCH), comprised of 24 international experts in underwater cultural heritage (UCH) who assist ICOMOS and UNESCO in promoting the protection and management of submerged cultural resources in inland and inshore waters, shallow seas, and deep oceans. A guide to best practices in UCH management and protection in territorial and international waters, the 1996 Charter was later largely adopted as the Annex to the UNESCO Convention on the Protection of the Underwater Cultural Heritage (2001), which provides an international legal regime for activities directed at submerged heritage (see Forrest 2010: 286–361). The guidelines established by the 1996 Charter serve to guard UCH from threats presented by commercial salvage and to harmonize the framework for protection of submerged sites with that already afforded to cultural heritage on land; as such, the 1996 Charter may be seen as a supplement to the ICOMOS Charter for the Protection and Management of the Archaeological Heritage (1990).

Definition

The 1996 Charter begins by defining UCH as "the archaeological heritage which is in, or has been removed from, an underwater environment," including submerged sites and structures, shipwreck sites, and their archaeological and natural contexts. UCH is further described as an international resource in character and often location, a finite and nonrenewable resource, a public interest, and a vehicle for knowledge about the human past.

The body of the 1996 Charter consists largely of 15 articles designed to ensure transparency and uniformly high standards in the aims, methodologies, and expected results of all investigations of UCH. Article 1 lists the fundamental principles for the protection and management of UCH, including a mandate to consider in situ preservation as a first option, alongside a preference where practical for nondestructive techniques of investigation over intrusive excavation. All projects that may encounter UCH should consider how to mitigate their impact on that UCH, avoid disturbance of human remains or venerated sites, and include adequate documentation. Public access to UCH is viewed as a primary aim of management and therefore encouraged. The remaining 13 articles provide detailed guidelines for responsible management and investigation of UCH when excavation or other intervention in a site is determined to be the best option. These guidelines consider: project design (Article 2); funding for all stages of the project, including conservation and dissemination (Article 3); timelines (Article 4); statement of research objectives, methodologies and techniques (Article 5); qualifications of investigating team, with direction by a qualified and experienced underwater archaeologist for all intrusive investigations (Article 6); site assessment for vulnerability, significance, and potential (Article 7); comprehensive documentation (Article 8); material conservation at all stages (Article 9); site management and protection including public information, stabilization, and monitoring (Article 10); health and safety of investigating team (Article 11); reporting of objectives, methodology, results, and recommendations for future research (Article 12); curation and scientific integrity of project archives (Article 13); dissemination of research for public awareness through presentations and reports, cooperation with local communities and interest groups, and research collaborations (Article 14); and international collaboration to promote high standards of investigation and research (Article 15).

These guidelines for protection, intervention, and research aimed at UCH seek to provide practical rules and professional guidance for archaeologists and national authorities in research, management, and the institution of policy. Because it addresses in situ preservation, site investigation, management, maintenance, dissemination, and public outreach, the 1996 Charter has implications not only for heritage professionals involved directly with underwater sites and finds, but also for those whose work engages with or otherwise has an impact on UCH, including tourism and

museum professionals as well as the public (Maarleveld in Couratier 2008: 50–62).

Key Issues and Current Debates

While the 2001 Convention functions primarily as a juridical document, its Annex, based on the 1996 Charter, aims to offer practical guidelines and best practices deemed by some to be the "heart and soul" of the 2001 Convention (See Petzet in Grenier et al. 2006: vii-ix). To facilitate its application, the Scientific and Technical Advisory Board to the 2001 Convention serves primarily to advise state authorities and to promote and define best practice; (Guérin and Egger 2010: 102). ICUCH acts on a practical level, offering technical expertise for the protection and management of resources underwater (Grenier et al. 2006: x-xv). The tenets of the 1996 Charter may serve to guide public policy on UCH by numerous agencies in states that, for various reasons, have not become signatories to the 2001 Convention.

The 2001 Convention entered into force for signatory states in January 2009; for non-signatory states as well, the principles expressed in its Annex and the 1996 Charter have been successfully enacted in various ways. Innovative approaches to in situ preservation of UCH have been undertaken by a variety of states, including the pioneering project at Red Bay, Labrador, Canada and the *William Salthouse* wreck in Victoria, Australia; trails at the Florida Keys National Marine Sanctuary; Ustica off Sicily and Baiae in Campania, Italy; Sebastos in Caesarea, Israel; and Ampurias in Catalonia, Spain. Metal cages above identified shipwrecks in Croatia and the video camera monitoring of wrecks in Sicily, for example, aim to allow diving access while preserving the integrity of sites; so too does the establishment of maritime parks for individual wrecks as at the site of the *Kronprins Gustav Adolf* off Helsinki (Finland) or the *Wellington* in New Zealand (Manders et al. 2008; Alves in Couratier 2008: 81–90. See also: http://www.unesco.org/new/en/culture/themes/underwater-cultural-heritage/about-the-heritage/dive-trail-in-situ-presentation/). Initiatives toward submerged and partly underwater museums such as the Baiheliang Museum at the Three Gorges in China, the half-submerged Guangdong Maritime Silk Road Museum in China, and the Alexandria Underwater Museum Project also hold potential to expand the range of possibilities for in situ preservation and display (Koschtial in Couratier 2008: 63–9; see also contributions by Xiurun (309–340), Fuchs (372–80) and Amin (381–89) in Shuguang 2011). Continued archaeological investigations of sites provide a basis for new research not only on seafaring practices, ship construction technology, and trade goods, but also innovative education outreach through their display in museums of maritime history and underwater archaeology that hold broad appeal for tourism (examples include the Mary Rose Museum (UK); the Vasa Museum (Sweden); the Viking Ship Museum in Roskilde (Denmark), the Bodrum Museum of Underwater Archaeology (Turkey), the Vancouver Maritime Museum (Canada), and the Western Australia Maritime Museum).

While it sets in situ preservation as a first option to be considered for the preservation and protection of UCH, the 1996 Charter neither prevents nor inhibits archaeological investigation (Manders in Couratier 2008: 31–41; Guérin and Egger 2011). The first principle requires investigators to consider the relative merits of in situ preservation versus intrusive excavation according to the individual circumstances of the site and any perceived threats. Such a principle does not deny the possibility of excavation if it serves as the better means of achieving research and mitigation objectives that fit within the parameters stipulated elsewhere in the 1996 Charter.

Perhaps, the most critical aspect of the 1996 Charter is its explicit prohibition against the disturbance of sites for commercial exploitation aimed at trade or speculation. Such activity, "intended to profit a few at the expense of many," is considered "fundamentally incompatible with the protection and management of the heritage" (Introduction). Article 6 stipulates, "All intrusive investigations of underwater cultural heritage will only be undertaken under the

direction and control of a named underwater archaeologist with recognized qualifications and experience appropriate to the investigation." This article places control over decisions regarding UCH in the hands of trained professionals engaged with the methodology and standards of working in the underwater environment, the research questions appropriate to the project, and the long-term stewardship and management of cultural heritage. As part of a broader scientific discipline, underwater archaeology means more than the retrieval of objects from the marine environment; the field is defined by investigative techniques, theoretical grounding, and a shared set of ethical principles (Maarleveld 2011). As a final protection against commercial exploitation of UCH, the 1996 Charter includes the important provision (Article 13): "The scientific integrity of the project archive must be assured; deposition in a number of institutions must not preclude reassembly to allow further research. Underwater cultural heritage is not to be traded as items of commercial value." These guidelines ensure that materials are not made inaccessible for future research or public appreciation through dispersal into private holdings. The 1996 Charter's provisions for qualified archaeologists and its restrictions against the sale or dispersal of objects do not explicitly restrict private for-profit contract services for site protection and mitigation by professionals provided that proper principles are observed and the heritage remains in the public domain. Rather, they establish a dichotomy between research and preservation objectives and commercial goals; intrusive excavation should not set the sale of artifacts as an end unto itself.

The ethical and practical framework established by the 1996 Charter also raises significant questions regarding the treatment of UCH that has been previously recovered by salvors as commercial goods. Recent salvage, display, and sale of objects from the *Titanic*, lying at a depth of 3,700 m on the Canadian outer continental shelf, or the Belitung shipwreck discovered off the coast of Indonesia with its cargo of ninth-century ceramics, have brought this controversy to the forefront of discussion (see Green 2011: 449–52; Dromgoole 2006). Both the *Titanic* and the Belitung wreck were salvaged according to contemporary national and international law, but such commercial salvage does not match the principles expressed in the 1996 Charter. From an ethical perspective, under what circumstances should this or similar material be published in academic journals or displayed in scientific or educational institutions, and how can research interests be balanced with site mitigation and public access? (Johnston 1993). Can archaeological and ethical standards of acquisition and display be compatible with commercial salvage operations and the financial challenges of research in the deep sea? (Greene et al. 2011; cf. Kingsley 2011).

For states that have not become signatories to the legal framework of the 2001 Convention, such ethical questions about protection, excavation, and the deposition of artifacts recovered from shipwrecks may be answered in part through the 1996 Charter. More detailed regulatory provisions and mitigation strategies might be useful and necessary in the future to address the growing dangers presented by certain modern practices of marine construction, mineral recovery, and trawl fishing, yet these threats do not detract from an overall framework of protection that sees commercialization of UCH as unacceptable. As a guideline for best practices – nonintrusive site assessment, effective protection and management, and archaeological excavation as necessary – the 1996 Charter aims to offer a coherent set of strategies for the preservation and presentation of UCH for states, professional researchers, as well as private interests and the public at large.

Chemical Survey of Archaeological Sites

Kara A. Fulton
University of South Florida, Tampa, FL, USA

State of Knowledge and Current Debates

Soils and sediments are altered by human activity. These alterations can be direct and/or indirect, physical and/or chemical, and can both result from the deliberate behavior of people or be caused inadvertently. Chemical alterations of soils and sediments are often subtle and complex to study since laboratory methods must be employed (Holliday 2004). Their study is based on the premise that repeated human activities generate specific chemical compounds. Like a magnet, the negative charge of soil particles attracts positively charged compounds and forms a strong bond. This bond is relatively resistant to horizontal and vertical movement and, therefore, very stable over time (Wells 2006). Studying chemical alteration of soils and sediments has been used for archaeological prospection (locating and/or delineating sites) as well as interpretation of spatial use and function. Chemical analysis is best used in combination with other methods, and it is a particularly effective approach to interpreting spaces that contain little to no material culture.

Human-induced chemical alteration of archaeological soils and sediments can include an increase in phosphorus (P) levels due to the deposition of refuse and waste. The work of Arrhenius, a Swedish chemist, is regarded as pioneering in its interpretation of soil chemical properties in terms of archaeological significance. While working for the Swedish Sugar Manufacturing Company and generating soil maps, Arrhenius (1929) observed that areas on which medieval occupation occurred had higher levels of P when compared with those which were unoccupied. Arrhenius (1963) later continued with archaeological soil studies, while other researchers – especially Eidt (1977, 1985),

who contributed important methodological developments from soil chemistry – aided in the development and application of field and laboratory techniques to detect archaeological sites based on soil P levels. Subsequently, P analysis has been used for various archaeological purposes throughout the world. For example, in Queensland, Australia, Mulvaney and Joyce (1965) used this method to show relative occupation intensity over time. In North Wilshire, England, Smith and Simpson (1966) utilized P analysis to determine the presence of perishable artifacts in burials. At the site of Roders Shelter, Missouri, Ahler (1973) examined activity intensity and demonstrated the correlation between levels of P and lithic debris density. Davidson (1973) reconstructed the evolution of a tell site and investigated population growth at the site of Sitagroi in northeastern Greece using P analysis. Also in Greece, Cavanagh et al. (1988) used P analysis to identify human occupation sites and their boundaries. In Mesoamerica, Parnell et al. (2002) examined the relationship between P and refuse disposal at Piedras Negras, Guatemala. Their research concluded that there was a positive correlation between ceramic density and P concentration and showed that in-the-field P testing can be used to identify middens and guide excavations. In South America and in Europe, research into settlement-related anthropogenic dark earths has examined links between high P concentrations and the presence of well-preserved, P-rich microscopic inclusions, especially bone (Arroyo-Kalin et al. 2008; Devos et al. 2009).

Investigations of chemically altered archaeological soils and sediments have expanded to include a variety of elements other than P. Multielemental analyses have allowed for the exploration of connections between specific human activities and the elements that they deposit. Along with P, archaeological investigations have considered calcium (Ca), magnesium (Mg), and potassium (K). Additionally, carbon (C) and nitrogen (N) are commonly examined in association with human activities and to a lesser extent sulfur (S), copper (Cu), and zinc (Zn) (Fernández et al. 2002; Woods 2003; Holliday 2004). Much of what we know about the relationship between these elements and human activities comes from various ethnoarchaeological and experimental studies on contemporary occupation floors. For example, Luis Barba and colleagues have worked with indigenous people in small, rural villages throughout Mexico to investigate the deposition of elements due to various household activities (Barba 1986, 1990; Barba and Bello 1978; Barba and Denise 1984; Barba and Ortiz Butrón 1992, Barba et al. 1995). Other ethnoarchaeological studies have focused on different parts of Mesoamerica including, Oaxaca, Mexico (Middleton and Price 1996), Guatemala (Fernández et al. 2002; Terry et al. 2004), and Honduras (Wells and Urban 2002). These studies have found connections between specific domestic activities, such as cooking, storage, and craft manufacture, and certain chemical elements, compounds, and soil properties. Information from studies of this kind can be used as tools to interpret chemical signatures on archaeological floors and thus interpret ancient activity patterns. For instance, areas near ovens, fireplaces, and hearths tend to have high pH values and low P concentrations while also maintaining high levels of Ca and carbonates. The presence of wood ash, possibly from a hearth or kiln, is associated with high levels of K, sodium (Na), and Mg. The deposition of extremely high levels of P can be associated with food and beverage consumption and preparation, with low pH indicating food consumption. Ca and strontium (Sr) have been associated with the preparation of corn, whereas iron (Fe) has been associated with areas used for processing agave leaves. The elements barium (Ba), manganese (Mn), and P have been shown to indicate organic refuse disposal, while mercury (Hg) and lead (Pb) have been demonstrated to be associated with craft production. Additionally, the deposition of iron oxide and mercuric sulfide suggests the use of certain pigments, such as hematite and cinnabar, which were used in ceremonial settings including burials and caches throughout Mesoamerica (Holliday 2004; Wells 2004; Wells et al. 2007). Elemental concentrations are often quantitatively measured in parts

per million (ppm) using inductively coupled plasma-mass spectrometry (ICP-MS) or inductively coupled plasma-atomic emission spectroscopy (ICP-AES). Results are interpreted using spatial geostatistics and quantitative assessment. Multielemental analysis has been applied to the interpretation of a multitude of archaeological contexts, including plazas, middens, marketplaces, palaces, underwater archaeological sites, and houselots, among other contexts (e.g., Anderson et al. 2012; Aston et al. 1998; Bintliff et al. 1990; Canuto et al. 2010; Cap 2015; Cook et al. 2006; Dahlin et al. 2007; Eberl et al. 2012; Entwistle and Abrahams 1997; Fernández et al. 2002; Fulton et al. 2017; Hutson and Terry 2006; LeCount et al. 2016; Lewis et al. 1993; Linderholm and Lundberg 1994; Luzzadder-Beach et al. 2011; Parnell et al. 2002; Rothenberg 2014; Sills et al. 2016; Wells 2004; Wells et al. 2007).

When interpreting concentrations of elements for archaeological purposes, it is not the absolute concentrations that are of interest, but rather the relative concentrations and spatial patterns of elements (see also Wells et al. 2000). By mapping concentrations of elements across archaeological surfaces, researchers can examine differences in spatial use as well as sometimes define areas where specific activities likely occurred. Paired with observations of traditional archaeological artifacts, important insights can be achieved into past activity patterns and human practices. It is thus unsurprising that chemical surveying of archaeological sites has become a popular technique in contemporary archaeological investigations.

Chicken: Domestication

Joris Peters
ArchaeoBioCenter and Department of Veterinary Sciences, Institute of Palaeoanatomy, Domestication Research and the History of Veterinary Medicine, LMU Munich, Munich, Germany
Bavarian Natural History Collections, State Collection of Anthropology and Palaeoanatomy Munich, Munich, Germany

Basic Species Information

The wild or red junglefowl *Gallus gallus* (Linnaeus, 1758) is the primary ancestor of domestic poultry. In areas where the distributions of the two species come into contact, red junglefowl is known to hybridize with grey junglefowl, *Gallus sonneratii* Temminck, 1813 (McGowan 1994). This happened in the past as well since domestic poultry acquired a gene responsible for yellow legs while retaining most of its genome from *G. gallus* (Eriksson et al. 2008). *G. sonneratii* is confined to Peninsular India except for NE India, where it is replaced by the much more widely distributed *G. gallus* occurring from India to S China and south across Thailand, Laos, Myanmar, Vietnam, Sumatra, Java, and Bali (McGowan 1994).

Major Domestication Traits

Red junglefowl are small-medium phasianids exhibiting a bright, colorful plumage in mature males. The species is characterized by a marked sexual size dimorphism (♀♀: 500–1050 g, ♂♂: 700–1450 g) (McGowan 1994). Domestic forms show a high variation in plumage color and may attain weights >5 kg. In all domestic breeds a clear sexual size dimorphism is observed. Like their wild ancestor, domestic chicken are opportunistic, omnivorous feeders. Their diet comprises a diverse spectrum of plant species as well as invertebrates. *G. gallus* breeds seasonally and can have up to three clutches of five to six, eventually up to nine eggs (McGowan 1994). Kept under natural conditions, *G. domesticus* can reproduce most of the year, except during winter when egg production ceases. Full clutches of domestic hens usually number about 12 eggs.

Genetic studies of modern wild and domestic *Gallus* indicate multiple maternal origins with possible domestication in the Indian subcontinent, SE China, and southern China and neighboring countries (Liu et al. 2006). However, this picture must be verified applying ancient DNA analysis because modern breeds may not be descended from local wild populations due to the introduction into Southeast Asia of more prolific, indigenous lineages during the last 200 years. Hybridization between wild, feral, and domestic *Gallus* has occurred as well, and fully wild red junglefowl is on the decline everywhere, if not already largely extinct.

Timing and Tracking Domestication

Written sources, iconography, and osseous remains of *Gallus* collected in archeological sites located beyond the natural distribution range of red junglefowl are indicative of domestic status. The earliest chicken finds come from sites along the Neolithic Yellow River and the Middle Yangtze (West and Zhou 1988). These findings would imply that domestication took place prior to 6000 BCE. This hypothesis must be verified based on a (re)evaluation of securely dated avifaunal assemblages. More than 3000 years later,

clay figurines and depictions of *Gallus* on ceramics illustrate the presence of domestic fowl in the Harappan sites (c. 2600–1900 BCE) of the Indo-Gangetic Plain. Trading contacts between the Indus Civilization and Mesopotamia initiated the westward diffusion of *Gallus* during the 2nd millennium BCE. From here, domestic chickens spread northward to the Caucasus region and westward to the Levantine coast. The fact that southern Mesopotamia was tributary to the Egyptian rulers explains why in the annals of Thutmose III (1479–1425 BCE) it was noted that the king received "birds which lay every day." Obviously, laying performance in chicken had already been improved considerably by human selection.

Since poultry can serve as living provisions on journeys, it is not surprising that seafaring people often carried chickens. Thus, early in the first millennium BCE, the Phoenicians introduced poultry keeping into their newly founded colonies located in coastal northern Africa and southern Spain, whereas the Greeks did the same in coastal and insular Mediterranean Europe. The need for provisions on sea journeys also explains the spreading of *Gallus* in Oceania since *c*. 3000–2800 BP and across Micronesia one millennium later (Storey et al. 2007).

If in the seventh–sixth centuries BCE domestic chicken made its appearance in temperate western and central Europe, poultry breeding only became popular under Roman cultural influence (27 BCE–478 CE). This trend is also observed elsewhere in the *Imperium Romanum*, e.g., in coastal N Africa and Egypt. Based upon currently available evidence, the diffusion of chicken husbandry into sub-Saharan Africa was a comparably late phenomenon starting in the fifth century CE.

While it is clear that European chickens were introduced into the Americas by Spanish or Portuguese explorers that arrived on the East Coast around 1500 CE, the presence of domestic fowl prior to this date remains a matter of dispute. An ancient DNA sequence and radiocarbon date from a single chicken bone excavated in coastal Chile has been interpreted as a Polynesian introduction in pre-Columbian times (Storey et al. 2007), but definite proof requires further analyses of ancient DNA sequences and radiocarbon and stable isotope data from archeological excavations within both Chile and Polynesia (Gongora et al. 2008).

A most remarkable aspect of domestic fowl is its role in symbolism and offerings in first millennium BCE Eurasia. Examples of this are the sacrifices in honor of Mercury, in the frame of the cult of Isis, and in Mithraism as well as its use in divination rites and as offerings with burials. Whether religious motifs initiated *Gallus* domestication or – as often stated in literature (Garrigus 2007) – if it were for the purpose of cockfighting, a pastime in the Indian subcontinent known since the first millennium BCE cannot be decided for the moment. Because neither the outcome of the domestication process nor the future needs of a society can be predicted by the domesticator, postulating intentional domestication is a critical issue because it is usually based on hindsight.

Interestingly, gut contents of 37 wild birds in India were noted containing seeds of 30 plant species including a single cultivar, i.e., rice (*Oryza*) (McGowan 1994). First domesticated in the Yangtze River valley 8000–6000 BCE, rice agriculture diffused to South China around 3000 BCE, whereas in the Indus Valley Civilization, rice cultivation can be dated to the 1st half of the third millennium BCE (Glover and Higham 1996), which is broadly contemporaneous to the appearance of domestic chicken in the local faunal record. It can therefore be questioned if innovative agricultural practice in Southeast Asia did not create a new feeding niche for *Gallus gallus*, thereby paving the way for a closer relationship between humans and red junglefowl.

Chickpea: Origins and Development

Leilani Lucas and Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

Basic Species Information

Chickpea is the cultivated legume, *Cicer arietinum* (L.). It is the only cultivated pulse from the tribe Cicereae (Family Fabaceae). Other names for this crop of Neolithic southwest Asian origin include garbanzo bean in the Americas, hamaz in Arabic countries, nohud or lablabi in Turkey, shimbra in Ethiopia, and bengal gram or chana in India (Redden and Berger 2007: 9). Chickpea ranks third in the world's production of seed legumes, after soybean (*Glycine max* L.) and pea (*Pisum sativum*). It is cultivated on nearly every continent, but major traditional production is in India, Pakistan, Turkey, Myanmar, and Ethiopia. Chickpea can be consumed cooked, baked, roasted, popped (like popcorn), stewed, or ground into flour (gram flour). The success of chickpea on a global scale is due to its high seed-protein content (nearly 20%) and, as a result, its potential as a valuable meat substitute. The high protein content makes it a perfect addition to cereals, as cereals are high in starch, and the combination of both of these provides a nutritional balance (Zohary et al. 2012). Kerem et al. (2007) have highlighted that chickpeas are especially rich in the rare amino acid, tryptophan, which may have made these of particular interest over other food plants. In addition to dietary benefits, pulses are useful when grown in fields together with cereal crops or when fields are rotated between the two. This is because pulses are able to fix atmospheric nitrogen in the soil, thereby replenishing nitrogen in soils depleted as a result of cereal cultivation (Zohary et al. 2012).

Major Domestication Traits

The seeds of chickpea are the most common plant part identified in archaeological contexts. The seeds of chickpea are dicotyledons, which can be divided into symmetrical halves. The morphology of chickpea seeds can be described as angular with wrinkly surfaces, with a defining characteristic, i.e., a protruding beak and a hilum under the beak (Fig. 1). Identification can be difficult due to fragmentation during charring and the specimens are then most likely to be identified to the family level (Tanno and Willcox 2006).

There are four primary changes in the evolution of chickpea under domestication. The first is

Chickpea: Origins and Development, Fig. 1 Sketch of the chickpea, including leaf and pod above and seed below. The seed is shown in basal view (with hilum), lateral view, and cross section showing the short embryo

an increase in seed size, which is most often the only surviving indicator for domestication in the archaeobotanical record. The second is the breakdown of the mechanism that retains the pod and seed on the plant. This allows the seeds to remain on the plant until the crop can be harvested as opposed to when the plant is ripe, as is the case for wild varieties. The third trait is a reduction of seed-coat thickness, which makes the seed coat more water absorbent and thus likely to germinate in the same year they are sown. This is in opposition to the wild types which have less permeable seed coats and as a consequence germinate over the course of several years. The fourth trait involves a change from autumn- to spring-sowing, which may be a result of the interaction between the pathogen *Digymella rabiei* and the fact that lengthened summer daylight enhances seed maturation (Zohary et al. 2012: 75–89, with references; Tanno and Willcox 2006: 197).

Timing and Tracking Domestication

The chickpea (*C. arietinum*) appears to have been domesticated from the wild *C. reticulatum* (Ladizinsky and Adler 1976; Zohary et al. 2012). The natural distribution of *C. reticulatum* is restricted to southeast Turkey, which provides the location of chickpea domestication and an area from which the crop spread (Fig. 2). The dispersal of domestic chickpea out of southeast Turkey resulted in the development of two crop types, the Kabuli and Desi, associated with the western and eastern dispersal, respectively. The Kabuli type (var. *macrocarpa*) is common in the Mediterranean countries and the Near East and has large, light colored owl-head-shaped seeds. The earliest well-preserved archaeobotanical evidence of chickpea outside of its wild progenitor's natural distribution area comes from a site located 260 km south of this region, in northwestern Syria. Charred remains from the early Pre-Pottery Neolithic B (c. 8400 BCE) site of Tell el-Kerkh provide evidence for an "intermediate" stage between the wild and domestic type morphologies (Tanno and Willcox 2006). There are specimens from Çayönü in southeastern Turkey that date to the same time and were found near the wild range of distribution, with likely later finds an indication of its spread to the southern Levant (Fig. 2). In general, finds of chickpea are rare compared to other

Chickpea: Origins and Development, Fig. 2 Map indicating the wild range of *Cicer reticulatum*, the general maximal extent of early/traditional chickpea cultivation and the distribution of representative early archaeobotanical finds (Based on data in Tanno and Willcox 2006; Fuller and Harvey 2006; Lippi et al. 2009; Zohary et al. 2012)

legumes, such as lentils or peas, which may indicate preservation biases against chickpeas. Nevertheless, the few finds indicate an early dispersal to the southern Levant and central Anatolia before 6000 BCE. Additional evidence for the westward spread include data from late Aceramic Neolithic Cyprus (c. 6500 BCE from Dhali-Agridhi), and finds from Greece just after 6000 BCE, with evidence from the Balkans by 5500 BCE.

The Desi variety (var. *microcarpa*) is associated with the eastern dispersal of chickpea and is common in India, Afghanistan, Ethiopia, and some parts of the Near East. This type is smaller and darker in color and has ram-head-shaped seeds (Ladizinsky 1995; Zohary et al. 2012). Evidence from the eastern margins of the Middle East is, so far, lacking of a comparable age to the evidence for the westward dispersal. So too is early evidence from the western Mediterranean. Nevertheless, finds from the Indus Valley, including specimens from Harappa, put cultivation in Pakistan by c. 2500 BCE, with further spread into India at c. 2000–1500 BCE (Fuller and Harvey 2006). In Egypt, chickpeas are known from the New Kingdom, e.g., the Tomb of Tutankhamun (Zohary et al. 2012). The earliest report thus far from Italy is of a Middle Bronze Age date (Lippi et al. 2009).

Childe, Vere Gordon (Political and Social Archaeology)

Randall H. McGuire
Binghamton University, State University of New York, Binghamton, NY, USA

Basic Biographical Information

Vere Gordon Childe (1892–1957) was arguably the most read and cited archaeologist of the twentieth century (McNairn 1980; Trigger 1980; Green 1981; Harris 1994). He produced broadly synthetic works that addressed fundamental questions relating to the pasts of Europe and the Near East, cultural evolution, and the nature of knowledge. He wrote in a clear way that appealed to popular audiences and to scholars outside of archaeology. Childe was an avid socialist and Marxist. In the 1930s, he recognized the role of prehistory in supporting the rise of Fascism in Germany. He asked and answered the question "Is Prehistory Practical" to challenge Fascism. After the Second World War, he confronted the Soviet perversion of Marxism and built an approach to knowledge to contest it.

Childe was born on April 14, 1892, in Sydney, Australia. He attended Oxford University in England, and in 1916, he earned a Ph.D. in classical philology. He returned to Australia where he became involved in leftist politics, and in 1921, the Australian Labor Party sent him to London as a correspondent. When the party suffered defeat the following year, Childe lost his employment and returned to an academic life in Great Britain. In 1927, Edinburgh University appointed him a full professor and granted him the Abercromby Chair of Prehistoric Archaeology. Childe was never an avid fieldworker, but between 1927 and 1954, he did excavations at seven archaeological sites in Scotland and Ireland. In 1946, the Institute of Archaeology in London appointed him Director and Professor of European Prehistory. He held this post until his retirement in 1956 when he returned to Australia where he died on October 19, 1957.

Childe's (1925, 1926, 1928, 1929) earliest research focused on the prehistory of Europe, the definition of archaeological cultures, and the diffusion of ideas in order to challenge nationalist and racist interpretations of European prehistory. Childe took his initial concept of an archaeological culture from the German archaeologist, Gustaf Kossinna. In his book *The Danube in Prehistory*, Childe defined an archaeological culture as a complex of types of remains including artifacts, house forms, and burial forms that consistently reoccurred together (Childe 1929: v–vi). Kossinna equated archaeological cultures with races, and he sought to trace the migration of the German race. Childe tried to counter this racist notion by demonstrating that archaeological cultures primarily changed due to diffusion and thus did not differ in terms of creativity, intelligence, or accomplishments.

In the late 1930s, Childe formulated his approach to cultural evolution. Childe (1934) first discussed agricultural and urban revolutions in his book *New Light on the Most Ancient East*, and he elaborated these ideas in his major popular work, *Man Makes Himself* (Childe 1936). He discussed cultural evolution in substantive terms to account for historical developments in the Near East and Europe. He did not engage in polemic nor did he develop a universal evolutionary theory.

Childe argued that archaeology should be a historical, human science. He recognized that archaeologists could learn a great deal from the natural sciences, but he rejected the idea that the methods or concepts of the natural sciences could be applied directly to the study of prehistory. For Childe, evolutionary laws did not transcend time and space. Universal laws or truths could only exist if human nature and/or society were fixed and immutable. Childe began with the Marxist principle that both human nature and society are constantly changing. Childe defined evolution as what happened in history. From a dialectical perspective, he saw no dichotomy between history and evolution, and he linked diffusion and evolution in his substantive studies.

After World War II, when the failings of the Bolshevism of the Soviet state became apparent to scholars in the West, Childe wrote about the nature of knowledge and its relationship to society. Childe (1989: 15–17) would later call Stalinism "the Marxist perversion of Marxism." With this critique, Childe became very concerned with epistemology, that is, with the nature of knowledge and how scholars create it. He rejected notions of laws that determined social change. He saw knowledge as complexly created and always subject to revision. His discussion of the nature of knowledge presaged current debates in Anglophone archaeology by a generation.

In Society and Knowledge, Childe (1956) argued that the function, structure, and content of knowledge are social and relate to action. Knowledge functions to provide rules for cooperative social action. The content of knowledge provides a working model of the "real world" that must be accurate enough for society to act. But, a society's knowledge is not always progressive, and scholarly critique reveals its conservatism. For Childe, the convergence between knowledge as a model of the "real world" and society's means of production provides the measure of a society's fitness to survive. Individual delusions or social illusions could hamper a society's knowledge or ability to act and progress (Childe 1956: 115). Such delusions may serve the particular interests of classes or specific groups and, at the same time, be a buttress to the authority of the ruling class. These delusions transform knowledge and science into ideology, and this ideology becomes a brake upon the progress of knowledge. Childe saw the development of knowledge as a dialectic in which people achieved understanding through the negation of error.

Major Accomplishments

Archaeologists continue to read, analyze, and discuss Childe (McNairn 1980; Trigger 1980; Green 1981; Harris 1994). The advent of radiocarbon dating in the 1950s revealed many of Childe's substantive interpretations of European prehistory to be false. His work, however, continues to be the starting point for questions of cultural evolution and domestication. Regrettably, Childe's discussions of epistemology have not received the attention of his other work. His observations, however, remain relevant and insightful as archaeology moves away from the sterile late twentieth-century debate between objectivist and relativist approaches to knowledge. Childe' ideas contributed to the three main archaeological movements of the twentieth century, culture-history, processual archaeology, and post-processual archaeology. Until archaeology transcends the issues raised in these movements, archaeologists will keep returning to Childe's work.

Childe, Vere Gordon (Theory)

Thomas Patterson
Department of Anthropology, University of California, Riverside, CA, USA

Basic Biographical Information

Socialist, antiwar activist, and social theorist V. Gordon Childe was probably read by more people than any other archaeologist of the twentieth century. Childe was born in North Sydney, Australia, on April 14, 1892, and, fearing ill-health and being a burden on society, committed suicide on October 19, 1957, near Sydney. He graduated from the University of Sydney in 1913 with honors in classical studies and received a scholarship to attend Oxford University from 1914 to 1916, where studies of classical archaeology aroused his curiosity about what happened before written records. Returning to Australia, he spent the next 6 years engaged in antiwar and progressive politics, serving as a secretary to the prime minister and later as a research and publicity officer in London. When the Labor government of New South Wales was ousted in 1922, Childe found himself without a job and with poor prospects of finding one in his home country and resumed his studies of prehistoric archaeology. For the next 5 years, he supported himself translating archaeology books into English and working as the librarian at the Royal Anthropological Institute. In 1927, he joined the faculty at Edinburgh University; in 1946, he became professor and director of the Institute of Archaeology at the University of London until his retirement a decade later.

Major Accomplishments

Childe's (e.g., 1925, 1926, 1929) studies in the late 1920s were concerned with cross-dating local cultural sequences from the Near East and Europe in order to explore changing relationships between the various cultures of this vast region. These studies heralded the replacement of nineteenth-century evolutionary schemes with culture-historical ones. Cultures, from his perspective at the time, were composed of objects and associations that repeatedly occurred together. He equated these with peoples and typically explained changes in terms of diffusion.

By the late 1920s, Childe had already begun to search the archaeological record for broader trends. In *The Most Ancient East* (1928), he argued that the development of agriculture (the Neolithic Revolution) marked a major change in human history. He adopted a version of the "oasis hypothesis" which argued that people domesticated the plants and animals that concentrated around water sources as the climate dried out at the end of the last ice age. In contrast to some advocates of this view, Childe argued that some

groups may have developed agriculture or animal husbandry, while others did not. In other words, these historical contingencies accounted both for the diversity of cultures with different economic bases and for the different trajectories of sociohistorical development that are evident in the archaeological record. They implied an ongoing dialectical relationship between human beings and how they perceived and used the environments in which they lived. Thus from his perspective, these contingencies and interactions precluded explanations of change that were based on either environmental determinism or unilinear evolution (Childe 1951).

From 1930 onward, Childe (e.g., 1930, 1934, 1936, 1942, 1946a, 1950, 1958) published a series of studies of the prehistoric past that focused less on culture-historical sequences and increasingly on economic relations. These ranged from the rise of craft specialization to the role of states, class formation, exploitation, and written records in the rise of civilization (the Urban Revolution). Many of the studies were simultaneously comparative and functionalist. His thesis of combined and uneven development was the first sustained socioeconomic analysis of the rise of civilization. He argued that (1) agriculture facilitated surplus production over subsistence needs and underwrote both technical and social divisions of labor; (2) the ruling classes in the Mesopotamian lowlands used part of the surplus they appropriated from direct producers to support full-time craft specialists, notably metalsmiths, who relied on ores obtained from the periphery; and (3) different trajectories of sociohistorical development emerged on the peripheries of the lowland Mesopotamian states.

From the mid-1930s onward, Childe framed his functionalist, socioeconomic analyses in increasingly Marxist terms (e.g., 1936, 1942, 1946b, 1950). He understood cultural change as a consequence of the contradictions that appeared between the forces and relations of production and that were manifested in the social organization, class conflicts, and world views of a society. These contradictions were the dynamic force of history – the motor that underwrote the dissolution of existing social relations and world views and the emergence of new ones in the larger totality we call society. This, of course, is the mode of production concept that Marx (1859) sketched in the preface of *A Contribution to the Critique of Political Economy.* During this time, Childe (e.g., 1954, 1956a) was one of the few archaeologists to point out that the rise of civilization had a dark side: exploitation, repression, and conquest, all of which impeded the growth of knowledge and progress by erecting ideologies (false consciousness) and practices that served the interests of ruling groups as exploitative social relations hardened.

Childe (e.g., 1946b, 1947a, b, 1956b) viewed archaeology as an historical science similar to paleontology or history as well as a social science, like anthropology, that attempted to understand ancient societies in the context of their historically constituted social relations and paths of development. From his standpoint, archaeological research was indispensable for providing information not only about past societies but also about long-term processes of cultural and societal change. Throughout his career, he increasingly saw change as a consequence of endogenous factors (the resolution of contradictions) rather a product of the migration of peoples, war, or conquest. His theoretically informed discussions of archaeology and past societies repeatedly challenged the hegemonic historical accounts and understandings of how humankind developed that were held by the ruling classes. As a result, he was continually aware of the difference between the evidentiary base that archaeologists use to discuss the historical development of human society, the methods they employ to accumulate evidence and bring these accounts to life, and the social and cultural milieus in which they present their findings and the discourses that these presentations engender.

C

Children in Bioarchaeology and Forensic Anthropology

Siân Ellen Halcrow and Stacey M. Ward
Department of Anatomy, School of Biomedical Sciences, University of Otago,
Dunedin, New Zealand

Introduction

The bioarchaeology of childhood has gained traction in the past two decades, with a proliferation of research papers and new methods for investigating this subset of past populations (Halcrow and Tayles 2008; Lewis 2007; Mays et al. 2017). It is now accepted that children are so-called "canaries in the coal mine" for population stress as a whole because their developing immune system and the energy requirements of normal growth make them more susceptible to the effects of stress (Lewis 2007). It is well established that children are sensitive barometers of population fertility, mortality, stress, and infectious disease, and their study also provides insights into identity and childcare practices in archaeological populations (Larsen 2015). Similarly, research on children in the forensic context is crucial given that infants and children are often the victims of homicide and genocide (Lewis 2007). For example, in 2012, children younger than the age of 20 comprised 95,000 or one-fifth of all homicides worldwide (UNICEF 2014). This entry introduces the bioarchaeological and forensic anthropological study of children and discusses key theoretical and methodological approaches and their limitations.

Definition

Bioarchaeology refers to the study of human skeletal remains from archaeological sites. This term was coined in the 1970s to refer to human skeletal analyses investigating the lifeways of past peoples, including diet, disease, migration, and habitual activities (Buikstra 1977). Child bioarchaeology therefore refers to the investigation of this age group from the archaeological context. The biological age categories that are used in bioarchaeology align somewhat with the medical literature. However, their use varies and Lewis (2007) and Halcrow and Tayles (2008) provide discussions of the different terminology used within bioarchaeology. Infants and children are often divided into the categories of fetus (younger than 37 weeks of gestation), infants (from the newborn period of older than 37 weeks to less than 1 year of age), and children (from about 1–17 years of age). Forensic anthropology refers to the investigation of human skeletal biology within the legal and/or criminal context. In the forensic literature, biological age at death for estimating chronological age is the primary identifier of children. Because of this, a major focus in childhood forensic research is the accurate estimation of age of infants and children using dental and skeletal methods (Lewis and Rutty 2003).

Historical Background

Early bioarchaeological research was focused on the description and typological classification of physical characteristics of humans based on adult skeletal (mainly cranial) remains. Although the concept of developmental plasticity and child growth was introduced in anthropology in the early twentieth century by Franz Boas, it was not until after the mid-twentieth century that infants and children were investigated in bioarchaeology, and until the 2000s that its study became more commonplace. Child forensic anthropology also has a relatively short historical background with the first forensic case studies occurring near the middle of the twentieth century (Lewis and Rutty 2003).

Key Issues/Current Debates

Bioarchaeological Theory: Stress, Developmental Origins and the Social Life Course

Bioarchaeologists traditionally employ a biocultural approach, where skeletal remains are interpreted within the context of the interplay between biology and culture (Larsen 2015). Physiological stress from an external (environmental) stressor is the central basis of this biocultural model (Goodman et al. 1984). Recently there is a growing interest in the Developmental Origins of Health and Disease (DOHaD) hypothesis in bioarchaeology, where it is recognized that maternal and early life stress has pressing implications for adult life and the health experience of their own offspring (Gowland 2015). Other approaches pertinent to child bioarchaeology are social life course theory and plasticity theory. The life course approach interprets aspects of human growth and health in the context of the different biological processes and social aspects that vary across the life course (Agarwal 2016). Plasticity theory views variability in development as a response to stress and investigates adaptive capacity across the life course. There is an increasing amount of literature drawing on social theory, focused on investigating the social identity of children, and the study of infant and child death and burial from archaeological contexts (e.g., Murphy and Le Roy 2017). Bioarchaeologists working with infants and children acknowledge that they are dealing with the nonsurvivors, and therefore, they may not be representative of the health experiences of survivors of the populations.

Methodological Approaches

The fields of bioarchaeology and forensic anthropology are similarly interested in building biological profiles of individuals, including age and any other identifying features such as disease and evidence for trauma. As such, many of the methods employed for this purpose are similar between these fields. There are several central methods for investigating children in the archaeological and forensic anthropological contexts, and we outline these below.

Preservation and Recovery

Although it is often assumed that there are issues with preservation of infants and children in the archaeological context, there are many examples of excellent preservation of children from diverse environmental contexts (Lewis 2007, p. 20). However, there is the potential for small developing bones from infants and children to be missed or damaged during excavation.

Age at Death Estimation

Age at death estimation is a first step in bioarchaeological analyses and forensic anthropology identification. Human age has social, biological, and chronological facets. The estimation of age at death in bioarchaeology relies primarily on the assessment of biological age using standards for dental and skeletal development. Accepted age at death methods include the use of long bone lengths (Cunningham et al. 2016), dental development and eruption (Ubelaker 1989), and the appearance and fusion of secondary ossification centers (Lewis 2007). As mortality is the ultimate expression of physiological stress, age at death profiles provide insight into population adaptation to the biocultural environment (Lewis 2007). Social age may be assessed with archaeological analyses of grave goods, mortuary practices and historical documents. These data may be informative of the place and role of children in society, cultural beliefs around care, and may also provide insight into social organization. A key issue surrounding age at death estimation is individual and population level variation in biological development. Methodological development in forensic anthropology is focused on increasing the efficiency and reliability of existing aging techniques in forensics (Schaefer et al. 2017).

Mortality and Demography

Although the death of an older adult may be expected, the death of an infant or child is generally the outcome of poor health or an accident. Just as the World Health Organisation uses mortality rates to gage overall population stress and disease, bioarchaeologists also use mortality rates as an indicator of population adaptation. The study of demography focuses on past population composition (e.g., age and sex), to infer aspects of population dynamics such as population growth and decline and fertility rates. Counterintuitively, fertility can be assessed by looking at the amount of infant and child death in a cemetery sample, as the more babies that are born the more are expected to be represented in the cemetery sample. However, unfortunately infants and young child are often excluded from many fertility statistics on the assumption that they will be under-represented in archaeological samples (Halcrow et al. 2017).

Nonspecific Indicators of Stress

As children are growing there is an opportunity to assess their experience of stress through an assessment of physiological disruptions in growth. Because the etiology of these indicators of stress is often not known in the archaeological context, these are termed "nonspecific." Common types of nonspecific indicators of stress include developmental defects of the dentition (Hillson 1996). The rate of dental development and formation is less affected by environmental stressors than bone growth. Therefore, comparing the lag in long bone growth with dental development can give insight into the experience of stress (Humphrey 2000). Newer methods for assessing infant and childhood growth include the measurement of vertebral dimensions (Newman and Gowland 2015). There has also been a focus in research on the timing of adolescence as a measure of stress (e.g., Lewis et al. 2016). We can also look at evidence for bony responses to inflammation (subperiosteal new bone formation) or nonspecific bone infection (osteomyelitis) (Lewis 2018). Although the assessment of physiological disruption is not always useful in some forensic contexts, the application of these types of techniques may prove useful in assessing forensic cases involving child abuse and neglect, although these methods are not definitive (Ross and Abel 2011).

Specific Infectious Disease and Trauma

There are many pathological conditions that can be found in infant and child remains (Lewis 2018). Some diseases may leave diagnostic indicators on the skeleton, and these may be studied in

conjunction with detailed age, sex, and contextual information to identify specific diseases and provide insight into aspects of the environment such as subsistence and diet, level of sedentism, and social identity (Lewis 2007, 2018). Examples of specific diseases investigated in children include smallpox, tuberculosis, and treponemal disease (Lewis 2018).

Increasingly, trauma analyses are being incorporated into childhood bioarchaeological studies. When investigated within a life course theory framework, trauma analysis can reveal information on violence towards children, caregiving, childhood occupation, and personhood in childhood (Lewis 2007, 2014, 2018).

A key issue in the paleopathological and forensic anthropology analyses of children is the difficultly differentiating pathological and normal bone growth, and the removal of skeletal evidence of trauma and disease through the rapid remodeling of bone (Lewis 2014). Care must be taken in child trauma analyses, as the high cartilage content and other properties of infant and child cortical bone influence the fracture types observed, their distribution in the skeleton, and the duration of healing.

Weaning and Diet

Weaning is the process of introducing solid foods into an infant's diet and moving away from an exclusively breastfed diet. The start of this process is significant as it increases the risks of mortality and morbidity in infants, as they are exposed to more pathogens through food and water and the possibility of nutrient-poor weaning foods (Katzenberg et al. 1996). Estimating the age of onset of weaning provides information on cultural beliefs about infant and childhood diet, subsistence and availability of suitable supplementary foods, and duration of breastfeeding can have a bearing on fertility. The pattern of weaning and diet may be assessed through analyses of the skeleton, including chemical signatures (isotopes) in teeth and bone (and sometimes in hair if preserved), and macroscopic and microscopic investigation of developmental dental defects and dental wear (Halcrow et al. 2018). Recent developments in chemical studies of infant human remains are also allowing identification of physiological stress events during childhood (Beaumont and Montgomery 2016).

Forensic Anthropology Identification of Infants and Children

As mentioned, children are subject to high rates of homicide and violence and are often found in skeletonized states due to their rapid decomposition (Lewis and Rutty 2003; Lewis 2007). Skeletal indicators of sex and ancestry are often used in conjunction with age estimates and trauma and pathology analyses to build profiles for their identification. Although it is relatively easy to estimate a biological age of infants and children compared with adults in the forensic context, the methods for identification of infants and children including the estimation of ancestry and sex are problematic (Lewis and Rutty 2003).

Morphologically based methods for sex estimation of infants and children are problematic as there is little sexual dimorphism present prior to puberty (Lewis and Rutty 2003; Lewis 2007). Ancestry is identified through analysis of metric and nonmetric dental traits in deciduous and permanent teeth, body proportions, and skeletal nonmetric traits. In addition, isotopic analysis of tooth and bone may be useful for revealing the geographic origin of the deceased. Traumatic injuries may be used in forensic contexts to identify cause of death or factors relating to death, and patterns of trauma on the skeleton can be used for personal identification (Lewis 2007). Ancient DNA methods are increasing in reliability and applicability and are decreasing in cost. These techniques may be useful for investigating sex, ancestry, and identifying familial relationships.

Children in the Central and Western Mediterranean, Archaeology of

Katherine V. Huntley
Department of History, Boise State University, Boise, ID, USA

Introduction

In the central and western Mediterranean, childhood was considered a distinct phase of life; the age at which children ceased to be children was likely fluid and may have varied depending on factors such as socioeconomic status and gender. Archaeologists have focused their research on the identification of children's material culture, the differences in the treatment of dead children, and the portrayal of children in iconography. Within the discipline of archaeology for this region, the term "subadult" is used to refer to the physical remains of individuals under the age of 18 years; it is not equivalent to the term "child," which refers to a sociocultural construct.

Definition

The term "child" in archaeology is generally regarded to imply an individual who is considered a child by his or her respective society. That is, to say, the concept of "a child" is regarded as a cultural construct involving individuals that are physically and socially dependent due to their physical age and cognitive state. Among the cultures of the central and western Mediterranean, childhood seems to have been regarded as a distinct life stage, though the precise nature of the age and social distinctions is one area of scholarly inquiry.

Though one of the key issues (see below) in the study of children in the central and western Mediterranean is the definition and identification of children's material culture, there are certain types of artifacts that archaeologists have determined that share an association with children. Archaeologists have focused specifically on games, toys, and infant feeders, all of which conform to modern notions of what constitutes children's objects, as the material culture of ancient childhood. In particular, there have been a number of studies and exhibitions of these artifacts in the past two decades (e.g., Ricotti 1994; *Jouer dans l'Antiquité* 2001). Dolls have attracted some of the most attention; the majority of research has focused on the form and possible intended functions of dolls themselves (Elderkin 1930; Mason and Simeoni 1987).

Iconography and burial evidence provide some tangible evidence of the association between children and particular types of artifacts, an association which in some cases is also bolstered by the

historical record. Transition periods are particularly visible; the early and mid-teens, around the onset of puberty, seem to have been a critical point in the lives of children. Items, such as amulets and dolls, mentioned in historical sources associated with childhood and coming of age ceremonies, are found in association with children as associated grave goods and in iconography. For instance, a study of grave goods found with young girls between the ages of 8 and 14 years posited that dolls deposited with them symbolized that the girls never achieved marriage in life (Martin-Kilcher 2000). According to historical sources, young girls would have dedicated their dolls to the goddess Venus just before they married (Persius *Sat*. 2.70). Figurines that were possibly dolls have been found at temples of Venus (Elderkin 1930). Other artifacts associated with children were protective amulets. Votive terracottas in the image of infants depict them wearing such objects (Coulon 1994; Ammerman 2007), and boys on Roman children's sarcophagi are portrayed wearing amulets known as *bullae* (Huskinson 2007: 331).

Burial evidence has also attested to the social distinctiveness of children. Subadults, in particular neonates and infants, are often underrepresented in cemeteries; they were often interred in separate locations. Some infant cemeteries have been excavated, such as the late Roman infant cemetery at Poggio Gramignano in Italy (Soren and Soren 1999) and the Yasmina cemetery at Carthage in North Africa (Norman 2003). The phenomenon of separate burial sites for subadults has been seen in mortuary sites throughout the world, though reasons for this may vary depending on culture and location (Becker 2007). They have been even found beneath the floors of houses in some of the western Roman provinces. Overall within different regions within the central and western Mediterranean, there were variations in the treatment of subadult remains.

In addition to determining relationships between children and material culture, the study of the iconography has yielded evidence of ideological and symbolic associations with children. For instance, circus scenes were frequently found on children's sarcophagi in Roman Italy. The circus, as a liminal place where supernatural forces played a heavy hand in fate, represented the connection between magic and children, liminal beings whose graves were sources of power for magicians. The spirits of children themselves could affect the outcomes of races and the well-being of the competitors (D'Ambra 2007). Funerary images and sculptures have also revealed a strong symbolic link between children and animals. Lizards, for example, which were frequently depicted in funerary art with the image of a sleeping child, may have symbolically represented the protectors of children (Sorabella 2007).

Key Issues/Current Debates/Future Directions/Examples

The issue of definition and identification of children's material culture is a key issue in the archaeology of the central and western Mediterranean. In all likelihood, children in this region lacked a distinctive material culture. For instance, human figurines may have served either as dolls or as votives (Shumka 1999: 617), as could other types of miniatures, such as pots (Kiernan 2009). Graffiti of alphabets can be associated with adult learners as well as children; both individuals of all ages would have made use of dice and gaming pieces.

Also of concern in the archaeology of children in the central and western Mediterranean regards their underrepresentation in cemeteries. Debate over whether this is actual underrepresentation due to sociocultural traditions or only the appearance of underrepresentation due to differential archaeological preservation concerning the survival of infant bones in the archaeological record continues to be debated (Blaizot et al. 2003). Some scholars have speculated that this is due to the relative fragility of children's small bones (Bourbou 2000: 187). Acidic soils can affect skeletal survival, and shallow graves of infants are more vulnerable to damage from plowing (Evison 1987: 146). Furthermore, imperfect excavation techniques can affect the recovery of the remains of infants and young children (Bello 2004).

Another key issue is the study of children's lives and activities (as opposed to sociocultural

constructions) in the central and western Mediterranean. The goals of such studies have been to understand children as active social agents. Little is known of the archaeology of children's day-to-day lives, including the activities they participated in, the places they inhabited, the people with whom they interacted, and their contributions to their communities. The lack of a recognizably distinctive material culture makes identification of their presence difficult in contexts where either the image or the physical remains of a child is absent. There seems to have been no space within a Roman house designated specifically for children, as one might expect in an Anglo-American home (Wallace-Hadrill 1994: 42). With the exception of a child's bed from Herculaneum (Wallace-Hadrill 1994: 113), both Pompeii and Herculaneum lack anything readily identifiable as children's objects: a study of artifact assemblages from 30 Pompeian houses did not yield a single identifiable "child's object" (Allison 2004: 155). As a result, there has been little work done on analyzing domestic artifact assemblages in the Mediterranean to look for evidence of children's activities (for an exception, see Johnson 2007 on the site of Karanis, Egypt). A study of children's graffiti in Pompeii and Herculaneum has shown that children had preferred smaller and obscured spaces within houses for more leisurely activities (Huntley 2010).

Chile, Archaeology and Indigenous Communities of

Patricia Ayala
Chilean Archaeological Society, Santiago, Chile
Abbe Museum, Bar Harbor, ME, USA

State of Knowledge and Current Debates

Introduction

After a long history of the denial and assimilation of indigenous peoples in Chile, the existence of ethnic groups in this country was recognized with the enactment of the Indigenous Law in 1993. Consequently, the Chilean State was assumed to be multicultural. This process was undoubtedly framed within a global context of the emergence of indigenous movements of the late twentieth century, in which indigenous leaders and intellectuals, as well as governmental and non-governmental institutions and organizations, and scholars from different disciplines were mobilized in Chile. This scenario implied a new ideological, legal, and institutional context in which the relations of the Chilean State with indigenous peoples changed, since the state moved from an assimilationist and integration policy to one of recognition and promotion of cultural differences. From a position of power different from that of previous years, Indigenous people emerged as agents of a multicultural patrimonialization, postulating a series of demands and leading struggles around the significance and power of their cultural rights and the resources existing in their territories. In this scenario, Indigenous peoples claimed their rights over Indigenous cultural heritage and their right to participate in the bestowing of meaning, production, and control over this heritage, as agents interested in archaeological heritage and discourses of the past. In a north-south view of the native territories of the indigenous populations in Chile, the currently recognized ethnic groups are Aymara, Quechua, Atacameño, Kolla, Diaguita, Mapuche, Kawésqar, and Yagán, as well as the Rapa Nui that inhabit the Easter Island in Polynesia. Although a significant number continue to live on their original lands, there has historically been a significant migration to nearby cities and even to the capital of the country: Santiago. According to the 2002 census, 692,192 people declared themselves to be indigenous in Chile, corresponding to 4.58% of the total Chilean population.

This essay analyzes the connections between archaeologists and indigenous people in Chile, addressing the Aymara, Atacameño, Mapuche, and Rapa Nui cases in particular, since more information about their heritage claims is available. In order to contextualize the development of archaeology, I discuss relationships between the state and the indigenous peoples and the legislation related to cultural heritage, as well as the dominant theoretical paradigms in the archaeological field. It also reflects on the articulations of this discipline with colonialism, nationalism, and multiculturalism. We analyze the different approaches from which indigenous peoples have been integrated into the archaeological field, concluding the existence of archaeologies committed to these societies. Finally, this essay addresses cases of reburial and repatriation in the multicultural era.

Colonialist and Nationalist Archaeology

In Chile, the first attempts to analyze the archaeological record occurred during the nineteenth century. Naturalists integrated ethnographic and archaeological studies in their research; they created a taxonomic system of nature ordering that was transferred and included the past and present of indigenous populations (Salazar et al. 2012). Although the contribution of the Chilean State was initially indirect, this changed in the late nineteenth century with the publication of José Toribio Medina's book: *The Aborigines of Chile* in 1882. This book analyzes the first settlements of the country and the Mapuche culture. To this growing interest and the state control of the indigenous past and the archaeological remains, the founding of the Museum of Ethnology and Anthropology in 1912 was added, as well as the law 651 enactment in 1925. Thanks to this law, the Council of National Monuments was created, the institution in charge of the national archaeological heritage up to the present.

From the beginning of the twentieth century, the Chilean State began to support and finance archaeological research in troubled territories. On the one hand, in the north of the country, there was a process of "Chileanization" after the War of the Pacific (1879–1884), a war with Peru and Bolivia, when Chile took control of the northern region of its present territory and embarked on the nationalization of Aymara and Atacameño populations. On the other hand, in the south, it continued with the "Pacificación de la Araucanía," a process through which the country continued taking over the Mapuche territory. From an assimilationist ideology, the indigenous populations were denied and considered in the process of disappearance or extinction. However, the nationalization project required a history that covered the pre-Hispanic origins of the inhabitants of those territories. In this way, an important scientific activity was developed with the arrival of foreign teams such as the French Scientific Mission, which carried out archaeological and ethnographic research in the north. Besides, in 1911, the government hired German archaeologist and ethnologist Max Uhle, who carried archaeological investigations and historical reconstructions in this part of the country. Due to Uhle's ethnic and culturalist interpretations and his definition of the Atacameño for pre-Hispanic times, these indigenous populations were conceived of as territorialized and to remain in the past. This contributed to the construction of a culturally homogenous nation-state of white-European matrix. Later, Ricardo Latcham contributed to the chronological, spatial, and cultural ordering of the Chilean prehistory and the indigenous groups that inhabited the national territory, highlighting his contribution to the Mapuche archaeology (Salazar et al. 2012).

In the case of Easter Island, which was annexed to Chilean territory in 1888, the earliest archaeological expedition in the twentieth century was carried out by English archaeologist Katherine Routledge (1914–1915). However, according to Vilches (2015) unlike other cases where the political manipulation of knowledge had a sound state control, archaeology on this island was an opportunity for the Chilean nation to take advantage without state planning. Most of the archaeological restoration projects have been at least co-financed with foreign funds, and Chile had the vision to support an activity that did not mean large investments. For other researchers, the early development of archaeology in Easter Island made it possible to know a past almost forgotten by the Rapa Nui population, which was considered to be in a process of cultural disintegration and depopulation since the sixteenth century, increasing from the eighteenth century with the island's discovery by the Western world (Cristino 2011).

From the perspective of the anthropology and archaeology of these times, indigenous populations were considered as objects of study, reminiscent of a past that it was important to know before it disappeared. Although the interests of the scholars of those times were eminently scientific, their interpretations were incorporated into political agendas and justified the national policy of denial, integration, and assimilation of indigenous peoples. In the north of the country, Gundermann and González (2009) argue that the anthropological balance of the situation of the Northern natives indicated their complete integration, in

the case of the *Changos*, or the presence of few survivors who were in a clear process of assimilation, in case of the Aymaras and Atacameños. Furthermore, Seelenfreud (2008) states that in the Easter Island case the ethnological works focused on the study of the megalithic constructions from a rescue point of view, considering the Indigenous subjects as living vestiges of a glorious and mysterious past, a society on the verge of disappearing or extinguishing, without giving much relevance to the social and political contexts in which the Rapa Nui people were inserted or of the westernization processes they were undergoing.

Archaeology at that time was characterized by a markedly asymmetrical power relationship between archaeologist and Indigenous populations, who from a position of structural subordination fulfilled a role of workers and/or "informants." The archaeologists were connected with state and/or private interests and were foreigners or professionals from Santiago City associated with the ruling class. In these circumstances, Chilean archaeology reproduced a colonial rationality, which not only pressurized and territorialized native societies but attempted to impose a Western knowledge and value to history, the past, and archaeological remains. Reproducing what has happened in other contexts worldwide, some of the archaeological practices that continued the logic of colonialism in Chile are the denial of the other as subject, the exile of Indigenous people to a remote past, and the rupture of their historical continuity: the digging, study, and exhibition of Indigenous ancestors and collecting, musealization, monumentality, and patrimonialization of the Indigenous past. Through its interpretations and legitimation of the state ownership of archaeological heritage, nationalist archaeology contributed to the construction of an imagined national community. In this case, directly or indirectly, archaeological knowledge and practice were used to shape the Chilean national identity and validate its power and authority in the definition and control of the past and Indigenous heritage. Archaeology contributed to the myth of origin of the Chilean nation-state, naturalizing and legitimizing its presence in indigenous ancestral territories, while the latter were assimilated or integrated into a monocultural society.

Archaeology as a discipline began its institutionalization in the 1940s and 1950s, mostly through studies carried out by the Natural History Museum, La Serena Archaeological Museum, and San Pedro de Atacama Archaeological Museum, whose investigators had different trajectories influenced by empiricism and cultural history. In 1959, the Regional Museum was inaugurated in the city of Arica, highlighting the work of foreign archaeologists based in the country such as Percy Dauelsberg, Oscar Espoueys, and Guillermo Focacci, pioneers in the development of Arica's archaeology. According to Romero (2003), the growing emphasis on the study of archaeological burial sites, in particular the Chinchorro mummies, generated wide expectations among the general public, in addition to promoting an external view of archaeology as a study of remote societies that have little or nothing in common with the present indigenous peoples. At the same time, the Museum of Arica worked with a group of Indigenous people of Aymara origin who helped as labor force during the excavations and in the conservation of materials and especially in passing of vernacular knowledge (Espinosa et al. 1998; Romero 2003). During the same period, Belgian priest Gustavo Le Paige developed his investigations in San Pedro de Atacama (Ayala 2008). The relevance of his work lies in the fact that he managed to establish, early and permanently, the scientific power represented by the museum he founded in the main Atacameño settlement. Even though Le Paige defended the idea of Atacameño cultural continuity, he conceived the idea of a population in the process of vanishing and reproduced colonial relations of denial by not considering the Atacameño beliefs in the "grandfathers or gentiles" and their opposition to excavating archaeological burial sites and displaying human remains in the museum. From the Atacameño perspective, the "grandfathers or gentiles" are entities from long bygone time, from a pre-Christian time, and the interruption of their rest and negligence in the performance of ritual offerings impels them to provoke diseases in the living; this is why they are respected and feared.

In spite of this, the archaeological work of Le Paige was supported by some members of the local community, whose expertise in archaeology and museology has been recognized at local and national spheres.

In Southern Chile, many of the sites studied in Mapuche territory were cemeteries excavated by foreign archaeologists, including those worked by Schneider in the Bío-Bío region (Paredes 2015). Although in the 1950s Menghin established a more detailed pre-Hispanic chronology and smaller-scale excavations, it was Gordon who worked with burial sites in a more systematic way since the late 1960s and early 1970s. In addition, like Le Paige, self-taught archaeologist Maya Calvo de Guzman lived in her study field and developed funerary archaeology. According to Adán et al. (2001), this researcher established a relationship with Mapuche communities that was far from being horizontal, because it was mediated by her position in local power relations as she was the owner of an important property in Calafquén.

As in the north and south of the country, in Easter Island, archaeological remains were used as exchange assets in national and international standards. As a result of the great scientific expedition (1934–1935) led by the French archaeologist Alfred Métraux, together with the Belgian archaeologist Henri Lavachery, two "moai" (large stone statue) were removed from the country. One "moai" was sent to the Royal Museum of Art and History in Brussels and another to the Louvre in Paris, in addition to many smaller artifacts (Seelenfreud 2008; Vilches 2015). Prior to this, this colonialist practice was reproduced by Routledge (1915) by taking a "moai" to the Pitt Rivers Museum in Oxford. The departure of these objects provoked an immediate reaction on the part of the Chilean State, which sought to exercise sovereignty over the island by early appointing Easter Island as a National Monument in 1935. Although archaeologists had so far assumed that the Rapa Nui people did not have any relationship to archaeological sites, Norwegian Thor Heyerdahl's stay (1955–1956) marked a major turning point in the relationship between researchers and Indigenous people, who were involved in the research process for the first time (Seelenfreud 2008).

During the 1960s and 1970s, the teaching of archaeology was institutionalized in several state universities, and its scientific authority was reaffirmed, shortly before the National Congresses of Chilean Archaeology began and the Chilean Society of Archaeology (1963) was formed. Since then, archaeology in Chile has been characterized by research teams mainly directed and integrated by national archaeologists and a limited presence of foreign professionals, except for Easter Island. At the same time, the New National Monuments Law was enacted (1970), and with this the state began to intervene directly in the control of archaeological heritage, declaring all sites National Monuments, not only imposing state ownership over them but also nationalizing them. That same year, the socialist government of Salvador Allende (1970–1973) took on political power. During his government the first Indigenous Law (17,729) of the country was passed, recognizing the existence of culturally differentiated communities, admitting a historical debt, and acknowledging their political participation (Bolados 2010).

During this government, the Latin American Social Archaeology emerged arguing that archaeologists as social agents should not only reflect on society but may even prompt social change (Salazar et al. 2012). The main centers of development for this form of archaeology were located at the south and the north of the country, following conferences given by Peruvian archaeologist Luis Guillermo Lumbreras in Conception in 1974. From this perspective, the prevailing cultural historical approach was criticized, and new ways of practicing the discipline were explored beyond the diagnosis of cultural phenomenon. In the north, some archaeologists developed research projects in which they dialogued and collaborated with indigenous communities, while others focused on the continuity of the Andean culture and its role in the transition to socialism. An example of this was the ethnoarchaeological investigations led by the "Grupo Toconce" in the north of Atacameño territory (Aldunate and Castro 1981). This research team led by Victoria Castro, Carlos Aldunate, and José Berenguer influenced later generations of archaeologists who created different lines of collaborative work

with indigenous people (Adán et al. 2001; Carrasco et al. 2003; Jofré 2003; Ayala et al. 2003; Ayala 2008, 2014). The research of this group was pioneering in the development of ethnoarchaeology in Chile, although its links with the trajectory of this subdiscipline in the Latin American context (Politis 2015) remain to be studied. In this case, the local perceptions of archaeological practice were considered when choosing the topics and study methodologies, since along the investigation process apprehensions of some inhabitants of Toconce were identified on the archaeological excavations. For Ayala (2008) these politically committed academic agendas can be framed in a nationalist archaeology that contributed in the construction and imagination of a national community in transit to socialism. However, it was also practiced in a cultural historical archaeology that did not consider the indigenous populations as valid interlocutors and with rights to have an opinion on the archaeological heritage. This is the case of San Pedro de Atacama where Le Paige continued excavating burial sites and spreading the "Atacameño Culture."

The socialist government was interrupted by the military regime in 1973, and Augusto Pinochet governed the country until the beginning of 1990. During these years, the "war" had a central role in shaping national identity, and military heroes became important symbols of the nation. The Chilean nationality was imagined as a homogeneous entity composed of a mixture of the best European values and the most heroic Mapuche warriors, who were valued for their arts for war and not for their cultural particularities. The authoritarian government was not interested in the figure of the Indian, except to denying it. Ethnicity was banished to the past, to folklore, and to museums; it was specified as a cultural heritage that should be represented and documented in writing but which had no present or future meaning. During this period, the previous advances made by the socialist government regarding the state's relations with the indigenous populations were disarticulated. According to Bolados (2010), during the dictatorship two decrees accelerated the process of division and liquidation of the communities from legal standards in 1979, since any state or private organism was allowed to tax the lands as they were not recognized as indigenous and their owners were not considered indigenous either.

The Pinochet dictatorship abruptly disrupted Marxist thought, interrupted the development of social archaeology, and closed archaeology majors in different universities. It also cancelled national congresses and controlled the theoretical reflection in the discipline. Despite the persistence of the historical cultural approach in different sectors of the country, New Archaeology gradually became the dominant paradigm. From this perspective research focused on problems related to the natural sciences, archaeological discourse was depoliticized, and new lines of study were opened. In part, this was the result of the concentration of political relations between Chile and the United States and the implementation of neoliberalism, which will keep Chilean archaeology away from the Latin American and, to some extent, European theoretical discussion (Salazar et al. 2012). It was during the dictatorship that archaeology was legitimated as a science, not only due to the influence of New Archaeology but also to the standards imposed to get research grants from the National Fund for Scientific and Technological Development, which followed the guidelines of north American capitalism.

In the north of the country, particularly in San Pedro de Atacama, archaeologists dissociated themselves from the social contexts in which they developed their research, assuming the neutrality of scientific discourse and ignoring the social and political impact of the discipline (Ayala 2008, 2014). As part of the disarticulations produced by the military coup, several professionals of archaeology from the university in Antofagasta were sent to the Museum in San Pedro de Atacama, which in 1984 was transformed into the Archaeological Research Institute and Museum Gustavo Le Paige. From a depoliticized approach to archaeology, the exhibition of this institution was renewed without breaking the preterizing device of exhibiting human bodies, and excavating archaeological burial sites continued. The relations between archaeologists and Atacameño people continued reproducing colonial logics of denial, although

some activities of diffusion and collaboration were conducted by archaeologists of the Institute.

In the south, from a perspective that combined archaeological, ethnohistorical, ethnographic, and linguistic information, North American archaeologist Tom Dillehay (2007) began his studies of settlement and subsistence patterns in the Purén and Lumaco valleys in the 1970s. He focused on the ethnoarchaeology of ceremonial complexes and burial mounds, his main source of ethnographic information being the "machis" (spiritual authorities) of some Mapuche communities. On the other hand, in the context of an incipient contract archaeology, a road project was carried out in the 1980s that sought to improve the connection to the south of the country, whose original design crossed Mapuche territory. This project was temporarily withheld, but the same people who put up the project at the beginning, a decade later, will raise the road modernization megaproject under the new label of Bypass Temuco. The Mapuche communities affected by this project were the WichanMapu1 of XufXufy Koyawe, who organized themselves to try to stop or modify the place where the new road intended to cross (Paredes 2015).

In Easter Island, from the 1960s to 1970s, the Chilean State began to invest in restoration work on monumental sites. This became a main source of paid labor for the local indigenous population. During these years, UNESCO specialists and the World Monuments Fund also visited the island to lay the foundations for a development plan based on the quality of its archaeological resources and the fragility of its environment. According to Seelenfreud (2008), each of these projects employed between 20 and 30 people for periods of between 6 months and a year. This situation marked the island's conception of archaeology: stable work well paid for a large number of people. However, since the 1980s, archaeology has been developed to solve problems and test hypotheses at the expense of mega-restoration projects. In this context, foreign professionals arrived who did not need the local labor force and did not have financing from the Chilean State or international organizations. The results of this change were felt in the relations between archaeologists and natives, who entered a conflicting arena with this new scenario.

Archaeology in the Multicultural Era

At the beginning of the 1990s all through the country, there were a series of social mobilizations claiming for the return of democracy after 17 years of dictatorship. Among the indigenous populations, the Mapuche movement played a prominent role, although it did not participate as a fundamental force of the opposition, but as an autonomous force working in coalition with others, but maintaining its own political identity. In the north, educated urban youths of indigenous origin in Arica, Calama, and Iquique organized themselves in protest movements, together with the political and social struggle against the military dictatorship. Participation, including the indigenous one, became one of the main emblems of the struggle against the military regime in the official discourse used by the coalition of democratic parties. However, discontinuity and discursive rupture in the political field consolidated in the opposition repression-dictatorship/participation-democracy. This did not mean challenging the neoliberal economic system instituted during Pinochet government but rather implied its continuity and partial measures that strengthened its development and consolidation in the years after the dictatorship (Bolados 2010).

The reconfiguration of the Chilean State in the democratic period goes hand in hand with the installation of neoliberal multiculturalism, which generates a new ideological, legal, and institutional scenario oriented toward indigenous peoples. With the participation and recognition of cultural difference as a new art of government, culture began to occupy a central place in public debate and in the identity construction of indigenous populations and the new Chilean nation. Since the state had previously disseminated a nationalist discourse of rupture between the indigenous past and present, the multicultural political discourse changed the relation of these populations with their past, when the Indigenous Law 19.253 suggested that the ethnic groups are

descendants of pre-Hispanic societies. This law also integrated Indigenous people to the national history, and this led Chilean people to reimagine themselves as a multiethnic nation and to reinvent themselves through a long-standing linear temporality, which places the pre-Hispanic past at the origins of the multicultural Chilean nation. On the other hand, the re-elaboration of the past of the ethnic groups in Chile has been a process of readjustment, tensions, and contradictions between the preexisting notions of identity, ancestrality, and temporality and those imposed by the multicultural state (Ayala 2014). In this context, we identify different sets of identities and temporalities operating within each indigenous group, which in turn have had different historical and political trajectories with the Chilean State. Along with this, their connections with the past, the archaeological heritage, and archaeologists differ from each other, since these are heterogeneous indigenous communities with their own political differences and internal struggles.

One of the first times archaeologists publicly faced indigenous questions was at the National Congress of Chilean Archaeology in Temuco in 1992, when two or three Mapuches burst into the Chilean Society of Archaeology meeting and confronted archaeologists about indigenous participation and authorization in their researches (Ayala 2008). Subsequently, representatives of indigenous populations expressed their demands and claims to the state and archaeology at public events, meetings, congresses, institutional documents, and publications. In the north, cultural heritage was approached as an Andean legacy that should form part of the Aymara and Quechua nations, including archaeological sites within some indigenous communities in the area, bringing to consideration the ethical aspects of the tangible and intangible heritage (Jofré 2014). On the other hand, in different contexts the Atacameño expressed their demands for the ownership and administration of the archaeological heritage, information on investigations, community permit to work, and indigenous participation in the disciplinary work, as well as not exhibiting human bodies or excavating archaeological burial places. Moreover, they sought to manage the Archaeological Museum of San Pedro de Atacama (Cárdenas 2001; Ayala 2008). In the south, Paillalef (1998) posed the problems observed in the conservation and protection of indigenous heritage and criticized the excavation of burial sites in Mapuche territory, highlighting archaeology's lack of consideration toward the interests of local communities. In Easter Island, Rapa Nui leaders criticized archaeological excavations, the study of burial sites, the lack of information on research, and the absence of community-based permits (Seelenfreud 2008).

Although the implementation of multiculturalism generated pressure to democratize access to the past and to the control of archaeological sites, the response of Chilean archaeology was delayed. In the academic field, the impact of this process was observed only in the late 1990s. In 1998, the book *Patrimonio Arqueológico Indígena en Chile: reflexiones y propuestas de manejo* was published as a result of reflection sessions held in Temuco in 1996 and 1997, which were attended by representatives of indigenous communities and government institutions, as well as researchers from different sectors of the country (Navarro 1998). At the end of the 1990s, articles on indigenous issues were published, in which a call was made to confront their problems and ask what archaeology has done in favor of the country's cultural minorities, as well as highlighting the need to establish more fluid connections between both parties and to take into consideration ethnic apprehensions about the excavation of archaeological burial sites (Cfr. Ayala 2003).

The initial response of the state to the indigenous demands was the execution of land registry projects and the preservation, conservation, valorization, and administration of archaeological sites for tourist use. This process involved the National Monuments Council, the National Indigenous Development Corporation, and the National Forestry Corporation, as well as regional museums and archaeologists. In the north a series of experiences of this type were carried out, especially the Atacameño case which was pioneer involving the village of Tulor, the Pukara de Quitor and Lasana, and the rock art of Peine (Ayala 2014). In Aymara territory, different

projects of land management and protection of pre-Hispanic sites were also carried out, highlighting those done in the Provinces of Arica and Parinacota due to the involvement of the *Pacha-Aru* Indigenous Association (Espinosa et al. 1998). According to Romero (2003), the National Corporation for Indigenous Development financed these projects within its development policy with identity, integrating these archaeological sites to the tourist and cultural market of the area.

In San Pedro de Atacama, in a scenario of disputes over the power of representation of the indigenous past and for the control, ownership, and significance of archaeological heritage, discourses were radicalized, and conflicts occurred in the execution of these heritage projects (Ayala 2008). Added to this was the destruction of archaeological sites in the construction of the Bypass San Pedro-Jama and the Gas Atacama pipeline. On the one hand, the archaeologists' response was to lock themselves in their academic bubble, not to get involved with the ethnic process, and to insist on a scientistic line of work that excludes, neutralizes, or invisibilizes the influence of the social context in the production of scientific knowledge. On the other, indigenous leaders contested archaeology by publicly criticizing archaeological practices and discourse. In addition, they banned access to the sites for some archaeologists and demanded the validation of their own professionals. Confronted by this loss of control, some archaeologists reacted by saying that they do not need community permission, that the property is owned by the state, and that the Atacameño do not understand scientific work. It was, then, a stage of disputes and conflicts in the multicultural heritage process, in which essentialisms prevailed and the relations of denial from archaeology were strengthened.

Meanwhile, in the south of the country, the Bypass Temuco environmental impact study was carried out by Geotécnica Consultants and the Institute of Indigenous Studies of the Universidad de la Frontera. It obtained a favorable resolution in 1999 despite the innumerable problems identified and evidenced by the Mapuche communities involved. Once the construction and execution of this highway was approved, the project affected 10 communities within the direct influence area and to 29 as part of the indirect influence area. In 2001, during the full development of the project, two pre-Hispanic burial sites were found, the human remains and archaeological objects were sent to Santiago, and this caused the Mapuche community mobilization who demanded their return. This materialized 3 months later, leaving the archaeological remains in the Regional Museum of Araucanía (Paredes 2015).

In Easter Island, there were conflicts between archaeologists and Indigenous people, although in this case the demand was to include the local community in the research projects. There are reports indicating that a team of foreign archaeologists was assaulted by a Rapa Nui group. This was difficult for team leader, an American archaeologist, to explain, who said they had done everything to establish a fluid relationship with the community, had all the National Monument Council permits, had incorporated a local researcher into the field work, and had a Chilean institution as an institutional counterpart. For Selenfreud (2008) these conflicts were directly related to the incorporation of tourists who pay to participate in scientific expeditions and a subsequent failure to call on local labor, over which in the past monumental restoration projects depended on.

In the year 2000, there was a significant change in national indigenous politics, consistent with a participatory multicultural discourse (Bolados 2010) and coinciding with a transformation in heritage management, which was assumed as state policy (Ayala 2014). This process involved the creation of new institutions, the discussion of renewed laws, greater and diverse access to economic resources, as well as the promotion of a discourse of "citizen participation" in the National Monuments Council. In addition, the Area of Indigenous Heritage in this institution has been created, in charge of promoting ethnodevelopment projects and ethnic professionalization. In the beginning, this area focused its actions in the north and south of the country, specifically in Atacameño and Mapuche territories, although it also executed some projects in Santiago with urban indigenous people and in

other regions as Arica and Chiloé. Unlike the heritage projects in Atacameño territory mainly oriented to archaeological sites, in Mapuche territory religious and ceremonial complexes of historical and ethnographic use were considered for their declaration as National Monuments. At the same time, the indigenous and intercultural policies that begun in the 1990s were deepened with the opening of the "Program Origins," financed by the government and the Inter-American Development Bank, whose implementation is directly connected with the aim of demobilizing and appeasing the Mapuche conflict that had again intensified at the end of this decade (Bolados 2010).

Chilean archaeology in the twenty-first century shows a more dialogic approach and search for common understanding, coinciding with the participatory multicultural discourse of democratic governments (Bolados 2010). As it will be seen in the following subtitle, this has materialized in the experiences of construction of a new type of relationship, in the integration of the indigenous voice, in the assessment of local histories and perspectives, and in the diversification of the spaces of diffusion of archaeological discourse. In this context, meetings for discussion were organized by indigenous groups, state agencies, universities, and/or archaeologists, such as the "Dialogue Discussion Boards" of the Archaeological Museum of San Pedro de Atacama (2000–2002) and the meetings held in Temuco (1998), Cupo (2000), Ollagüe (2001), Lasana (2003), and Caspana-San Pedro (2005). On the other hand, forums and discussion groups or symposiums were held in national and international congresses. This is the case of the symposium "Indigenous Peoples and Archaeology" of the 51st International Congress of Americanists (2003), the forum "Indigenous Communities and Archaeological and Anthropological Research" of the XVII National Congress of Chilean Archeology of Valdivia (2006), the symposium "Towards a Public Archaeology" of the XIX National Congress of Chilean Archeology of Arica (2012), and the symposium "Theory and archaeological practice and its relation with the indigenous communities in Contemporary Chile" of the XX National Congress of Chilean Archeology in Concepción (2015). In addition to the 2nd Archaeological Theory Workshop in Chile held in San Pedro de Atacama, and the VII Meeting of Archaeological Theory in South America (2014) based in San Felipe, archaeological work related to this subject was presented.

However, despite this participatory archaeological discourse and the deepening of multicultural politics, conflicts continue between archaeologists, indigenous peoples, the state, and/or private companies. This is the case, for example, of the UNESCO-JAPON Project for the conservation of archaeological sites in Rapa Nui (2005), which involved a majority participation of islanders in restoration and preventive maintenance work. However, the fact that this did not become a permanent program with the support of the state revived the distrust of the Rapa Nui population regarding Chile's lack of commitment to the island and the rejection of archaeologists who do not integrate members of their communities in their research (Seelenfreud 2008). In Atacameño territory, the accidental discovery of an infant and its offerings in the framework of an environmental impact project generated a series of disputes over the power of decision on indigenous archaeological heritage, despite the participation of community visitors in the work done in the field site (Rodríguez and Villaseca 2015).

Toward a Collaborative Archaeology

Though more recent advances in the relations between archaeologists and indigenous communities in Chile are fundamentally visible in congress presentations, project reports, and pre- and postgraduate theses, there are still few publications on this matter. This may be due to this discussion is still marginal in Chilean archaeology or because those in charge of initiatives of this type choose do not to publish their results in mainstream journals, either because they do not consider it necessary or because they oppose the academy as legitimating instance of scientific discourse. In addition, the fact that the author of this paper lives outside the country limited her access

to a greater amount of information. However, there are a number of works that, although they do not constitute a unified body of experiences of public, social, collaborative, indigenous, or decolonized archaeology, show the presence of these theoretical-methodological perspectives in Chile, at least in Aymara, Quechua, Atacameño, Mapuche, and Rapa Nui.

As has been discussed by Castañeda (2008) for other contexts, in Chile there has also been an ethnographic turn in archaeology as a way to facilitate relations between archaeologists and indigenous peoples, mitigate the effects of research, address ethnic demands, include other voices, and enrich the archaeological interpretations. Within this context, archaeological projects are identified in which anthropologists were involved to undertake – exclusively or partially – building or maintaining relations with the indigenous communities involved. This is the case of a project developed in the town of Ollagüe, in Quechua territory, in which an exercise related to the contingency was chosen, carrying out a series of actions aimed at closing the gap between archaeologists and indigenous communities (Ayala et al. 2003). From a social archaeology perspective and using ethnographic tools, bonds were built with the Quechua community to later train, renovate the local museum, and hold a meeting of reflection among ethnic representatives, archaeologists, and state agents. Besides, in the framework of an archaeological investigation of the recent past focused on the period of capitalist expansion in San Pedro de Atacama, the study of material culture was accompanied by an ethnographic research that contributed both to the collection and interpretation of information and to the construction and strengthening of community relations (Vilches et al. 2015). In the south of the country, the creation of a space of communication between scientists and Mapuche communities within research projects was made possible by the application of an ethnographic methodology that extended the field work and its results to the surrounding communities, favoring instances of dialogue in which archaeologists and anthropologists benefited as well as community members (Adán et al. 2001).

This ethnographic shift is also observed in projects in which the archaeologists themselves performed the ethnographic research. This is the case of Jofré (2003), who from an ethnoarchaeological approach carried out a project aimed at assessing the valuation and ethnic identification with the archaeological heritage of Belén. In her most recent research, she conducted an ethnographic research on Aymara indigeneity policies and property rights in the Lauca Biosphere Reserve (Jofré 2014). On the other hand, by applying ethnoarchaeology and recognizing the rights of the original populations as heirs or depositories of archaeological heritage, in the upper and lower basins of the Loa River and the oasis of San Pedro de Atacama, "low impact" archaeological investigations were conducted. This implied validating the opinion of indigenous populations emphasizing the study of collections and the excavation of settlements, as well as developing diffusion, documentation, and organization of storage spaces in local museums (Adán et al. 2001; Carrasco et al. 2003). From an approach that gathers the contributions of collaborative and decolonial archaeology and discussions of ethics in archaeology, Kalazich (2013) carried out a participative action research with the Atacameño community of Peine. In this investigation the main techniques of collecting information were applied ethnography and interviews.

Ethnography has also been used by archaeologists to study archaeology itself. This is the case of Cárdenas (2001), an Atacameño archaeologist who analyzed the perceptions of his community on the treatment of cultural heritage in San Pedro de Atacama. He concluded that there is discontent on the part of the Atacameño people regarding archaeological work and that there is lack of consideration for their communities, as well as for their disagreement with the excavation of archaeological sites and the exhibition of human remains in the local museum. In addition, in the field of ethnographic archaeologies, Ayala (2008) studied the history of the relationships among archaeologists, indigenous people, and the state in San Pedro de Atacama. She systematized Atacameño criticisms and patrimonial demands and

characterized different types of relationships between these three actors, concluding that it is the colonial bonds of denial that have produced conflicts between them. Subsequently, broadening and deepening this research, Ayala (2014) researched the ethnography of the practices and discourses through which the Chilean State is represented as multicultural and as a multiethnic nation. She also undertook an ethnographic archaeology that focused on the power devices of Atacameño archaeology and its connections with colonialism, nationalism, and multiculturalism. In the south, Paredes (2015) studied the relationship between the state, physical anthropology, archaeology, and members of the Mapuche Lafkenche people, specifically regarding the heritage management of human remains. She concluded that there is a general disapproval of the anthropological and archaeological practice among her interviewees and that in the case of some approval assessments, these are subjected to the need for informed consent from the communities. According to Paredes, the indigenous perception of researchers' abuse responds to their ancestral connection with human remains, given mainly by the cohabitation of the territory and the extensive family configuration of the Mapuche people, as well as by a very complex symbolic framework. This connection is also claimed by Mapuche people who migrated to the VII region of the Maule, where the Folil Mapu community demands their participation in the future of the archaeological site of Tutuquén. This community considers this place as part and representative of originary people they believe they have the mission and the responsibility to protect the territory where their ancestors are resting (Campos and Vergara 2015). On the other hand, placed within an intersubjective ethnography, Arthur (2014) carried out an investigation on the repatriation process in Easter Island. She argued that the Rapa Nui's understanding of their ancestors comes in conflict with the scientific view, since they have their own ontology, different from that influenced by Western society, in which the "ivi tupuna" are ancestors with whom they are related genealogically. According to Arthur, scholars have frequently ignored this distinctive ontology by promoting an academic tradition that objectifies the Rapa Nui system of knowing and relating.

There are also publications on the relations between archaeologists and natives based on a reflective analysis of the history of archaeology rather than on ethnographic data. This is the case of Romero (2003), who concluded that historically there has been little development of bonds between archaeologists and indigenous populations from the Provinces of Arica and Parinacota. He argues that archaeological research has not considered the original peoples either as recipients of their knowledge or as sources of research that could be incorporated by ethnoarchaeology. Besides, Seelenfreud (2008) evaluated the impact of the history of archaeology in the way the Rapa Nui population conceives archaeologists today. According to Seelenfreud, what were constant throughout the history of Easter Island have been the transgressions to the informed consent of the local community, as well as to the respect for the intellectual property and to the bioanthropological and archaeological resources.

The experiences of education, diffusion, and management of archaeological heritage are also present in projects with indigenous communities in Chile, forming a public archaeology characterized by a more practical than critical or multivocal orientation (Merriman 2004), although there are some exceptions (Marcos 2010; Alvares and Godoy 2001; Godoy et al. 2003; Vilches et al. 2015). In this context, projects for the valorization, protection, conservation, and administration of archaeological sites for tourism use throughout the country have increased (Espinosa et al. 1998; Bravo 2003; Jofré 2003; Ayala 2008; Urrutia 2014). This is generally associated with programs of indigenous professionalization (Ayala 2014). At the same time, the application form for the National Fund for Scientific and Technological Development includes a section devoted to diffusion to society, which should describe an extension activity for the nonspecialized public. In indigenous territories, the diffusion has varied from briefings on the activities and scope of the research to educational talks or training courses on local archaeology. A process that, in certain

cases, has exclusively involved indigenous leaders and in others students or people interested in heritage. In some contexts this diffusion has been carried out in association with museum institutions, such as the Archaeological Museum of San Pedro de Atacama where the Andean School heritage educational program (2001–2010) was developed for the Atacameño and Quechua population (Ayala 2008; Marcos 2010). Throughout 9 months a year, this school taught cultural management, ecology, tourism, archaeology, history, anthropology, indigenous legislation, conservation, and project formulation. In her analysis of the Andean School, Marcos (2010) concluded that despite its achievements in the dissemination of archaeological discourse, this initiative continues to reproduce colonial relations between archaeologists and Atacameños, since it legitimizes the discourse and authority of archaeology in a dynamics of unidirectional communication derived from the reproduction of its place of enunciation. Moreover, in the south of Chile, experiences of heritage education with Mapuche Huilliches communities were conducted, integrating oral history, material culture, anthropology, and pedagogy (Alvares and Godoy 2001). Some of these activities were carried out in museums under the Museum Direction of the Universidad Austral de Chile, while others were undertaken in local schools or in the archaeological field. According to these investigators, unlike ethnoarchaeology, these are experiences of social intervention where the theoretical and methodological corpus of anthropology is put at the service of the community. Its purpose is to contribute to community development by strengthening its identity through the enhancement of its local cultural assets and knowledge. For this team, heritage education presupposes a political positioning, in circumstances where educators not only fulfill the role of facilitators, but their mission extends to the consolidation of a meeting space and social dialogue whose purpose is to contribute to the legitimate exercise of cultural citizenship. To the contrary, these actions must motivate the exercise of cultural citizenship, that is, that Chilean society manifests itself in its multicultural essence (Godoy et al. 2003).

The integration of members of indigenous populations into archaeological research and environmental impact projects lies in the broad spectrum of Colwell-Chanthaphonh and Ferguson's (2008) *collaborative continuum*, whose three stages of development are resistance, participation, and collaboration. The dynamic character of the *collaborative continuum*, with its different degrees of involvement and upward commitment, makes it possible to understand the bonds between archaeologists and indigenous peoples in recent years as a process under construction. Throughout this paper, several examples of the resistance phase were described, so the specific phases of participation and collaboration will be discussed below. For some work teams, indigenous participation has taken place exclusively in information meetings or diffusion activities; other archaeologists also consider the application for community permits and the selection of problems and methods of study taking into account the criticisms and ethnic demands, which in some cases is associated with indigenous participation in different stages of the research process (Alvares and Godoy 2001; Adán et al. 2001, 2003; Godoy et al. 2003; Carrasco et al. 2003; Seelenfreud 2008; Ayala 2008; Marcos 2010; Kalazich 2013; Vilches et al. 2015). In contract archaeology projects, some members of the communities have participated in surveys, excavations, and laboratory work, as well as diffusion activities and informational meetings. Certain investment projects have had community observers or visitors in the field, as well as visits by indigenous leaders (Salazar 2010; Rodríguez and Villaseca 2015).

When analyzing the spaces of indigenous participation open by archaeology in the multicultural era, the educational, public relations and management of archaeology aspects stand out, which has been installed as the new disciplinary format and the "must be" for many professionals. This tendency conforms to what Ayala (2014) defines as multicultural archaeology, an approach which recognizes the other, opens archaeology to his/her participation, or accepts the indigenous property of heritage. However, this ends up being mere formalisms to continue practicing an archaeology rather than questioning its power and

place of enunciation. It is a traditional archaeology that conforms to the mandates of multiculturalism, a waist adjustment characterized by talks and diffusion courses that promote "restricted and controlled indigenous participation" (Bolados 2010). Eventually, this is followed by the participation of community members as labor in the excavations and the cleaning of materials, without having a voice in the design, formulation, development, interpretation, and/or results of the project itself or in the taking of decisions on recovered collections. However, it is also true that multicultural archaeology has opened up spaces of indigenous participation that did not exist previously, as well as debate on the social and political consequences of archaeology and has highlighted the difficulties of articulating theory and practice in building new relations with communities.

Next, experiences that distinguish a greater degree of indigenous involvement are discussed and are situated in what Colwell-Chanthaphonh and Ferguson (2008) describe in the range of collaboration. These are projects that also promote greater reflexivity and point to restructuring or decolonizing the discipline and its power relation transformation. This line includes Jofré's (2012) work with the Aymara communities of the Arica and Parinacota high plateau, who had to agree on their interests with archaeologists, government agencies, and private companies in order to achieve the community administration of historical monuments (Jofré 2012), as well as the "Abra Project" in Atacameño territory, whose long period of development in the framework of an environmental impact experience had affected the ensembled work and mutual benefits among members of this ethnic group, archaeologists, and mining officials (Salazar 2010). In addition, the research of historical archaeology developed by Vilches and collaborators (2015) in San Pedro de Atacama, in which the local relevance of concepts and theoretical approaches originated from public, decolonial, indigenous, and collaborative archaeologies, was discussed. In this project, entirely proposed from the academy, the local participation was achieved in the field work, laboratory, compilation, analysis, and/or integration of the information, as well as in informative meetings and request of community permission. Then again, there is the participatory action research carried out by Kalazich (2013) in the Atacameño community of Peine. From this perspective, the research problem and objectives were defined jointly with members of the local indigenous community and approved in a community assembly, as well as the results and the manuscript of this thesis. As participatory action research is one of the approaches used as part of the decolonizing of archaeology in the last decade (see Atalay 2006; Silliman 2008), Kalazich's work involved sharing power in decision-making, moving away from traditional methods of archaeology, and moving its place of enunciation, choosing the construction of collaborative and horizontal relationships.

Moreover, archaeological projects have been developed by indigenous communities themselves. This is the case of the experiences described by Urrutia (2014) for the Aymara communities of Camiña and Nama, the first of which requested an anthropological study that allowed defining its ancestral territory and the second a project to protect archaeological sites located in their territory. Through a process of dialogue in which the expectations of all members were coordinated, archaeologists, anthropologists, conservators, and architects worked together with members of the communities involved. They considered participatory strategies in all the activities of the project. Another group, the Atacameño communities of Coyo and Quitor requested professional advice to the Archaeological Museum of San Pedro de Atacama for the opening of site museums (Ayala 2008). Community assemblies discussed, defined, and approved what to exhibit and inform in these museum spaces, in addition to participating in workshops of archaeology and conservation. Another type of consultancy is related to the evaluation of environmental impact projects, in which archaeologists of this museum presented arguments to support community claims for hotel, tourist, road, mining, or energy investments. There is also the archaeological contribution in the legal recognition of Atacameño communities before the state (Ayala 2008; Salazar 2010). The Aymara community of Quillagua also

managed a project of valorization and heritage rescue to mitigate the intervention and looting of an archaeological burial site (García et al. 2012). From the articulated work of community active members, professionals, and state agencies, it was possible to generate an important collection of heritage material that was submitted to basic procedures of conservation. As the final stage of this project, a part of the human remains rescued was reburied. In the south of Chile, Mapuche communities of Chilcoco, Huenteldén, and Tirúa requested the collaboration of archaeologists in territorial claims. For Hermosilla (2015) there are cultural heritage valuations made from an archaeology enriched with participatory action research, involving interest groups and carrying out archaeology of the recent and contemporary past. On Easter Island, members of the Rapa Nui community asked for professional support for their repatriation project, care, and reburial of human remains, a process in which Arthur (2014) has collaborated from his expertise in oral tradition, history, and Rapa Nui land and heritage.

Repatriation and Reburial

One of the results of multiculturalism and indigenous claims in Chile has been requests for repatriation and reburial of human remains and archaeological objects. In this process of patrimonialization, the state has exercised its power through governing the bodies of their ancestors, since it is still in their power of naming that the procedures are regulated and it is decided who is authorized and legitimated to reclaim the bodies and rebury them, as well as who is their rightful owner (Ayala 2014). Although Chile does not have a law in this respect, from 2009, the Council of National Monuments has an "Instructive guide for the re-burial of human remains coming from archeological contexts, at the request of communities and organizations" (Gonzales 2008; Arthur 2014).

The first repatriation process occurred in the 1980s long before the enactment of the Indigenous Law in 1993 and the impact of the NAGPRA Act of the United States, enacted in 1990. In this case, members of the Atacameño communities requested the return of an archaeological collection sent to the National Museum of Natural History in Santiago (Ayala 2008). Something similar happened in 2001 when Mapuche communities demanded the return of human remains found in the archaeological excavations of Bypass Temuco that were transferred to the same city (Paredes 2015). These experiences served as antecedents to the later repatriation and reburial of human remains culturally linked with Aymara and Atacameño populations. Its execution was subject to an agreement signed between the Council of National Monuments and the National Museum of the American Indian of the Smithsonian Institute, as well as an agreement between the Council and the communities involved (González 2008). In 2010, the University of Zurich in Switzerland repatriated the remains of five Kawésqar individuals to their home community in Tierra del Fuego, in Chile's extreme south. In 2011, the Museum of Ethnography in Geneva, also in Switzerland, repatriated four mummies to the Miguel de Azapa Museum in Arica. A recent case of reburial is within the Aymara community of Quillagua, which worked together with archaeologists, curators, and state agents to value, protect, and preserve a funerary archaeological collection that later remained under the protection of their community. As a final step of this project, part of the rescued human remains was reburied in the cemetery at a ceremony organized and presided over by the local indigenous community (García et al. 2012). Another reburial that had state approval is that of the Atacameño community of Taira, which was carried out as part of an environmental impact study financed by the mining company CODELCO (Rodríguez and Villaseca 2015). Negotiations and the search for consensus between this company, government agencies, and the Atacameño community of Taira lasted for several months, as indigenous leaders established a series of demands regarding the treatment of the human remains and their funeral context, trying to achieve the maximum of return and the minimum possible intervention, in view of the final act of reburial.

In contrast to these experiences regulated and controlled by the Council of National Monuments, in the late 1980s, a reburial led by members of the Atacameño community of Chiu Chiu, without the authorization of this institution, was carried out (Ayala 2008). Something similar began to happen in the south of Chile, where due to the perception of some Mapuche community leaders that the patrimonial legislation does not protect them like the rest of the Chileans, actions have been carried out for self-protection of property without the Council's permission (Paredes 2015). On the one hand, this has resulted in the refusal to report the discovery of human remains and archaeological artifacts to the authorities, opting for their conservation "in situ." On the other hand, if the removal has been carried out, they could opt for the conservation of the pieces in the localities where they were found, and they would be administered by the communities, a situation that is only applicable to material remains and not to human remains, as they prefer not to disturb them. Besides, since 2013 the Rapa Nui have an independent and autonomous program of repatriation, care, and reburial of "Ivi-Tupuna" or human remains. It is an experience created and managed by members of the Rapa Nui community, working in collaboration with the Anthropological Museum Padre Sebastián Englert and researchers (Arthur 2014). Their more advanced repatriation case shows a series of difficulties with the Council of National Monuments, which seeks to regulate the procedures and reaffirm the national ownership of human remains and validate the scientific vision. For the Rapa Nui people, these human remains must be returned directly to the community without conditions or imposed regulations, since they are not the property of the nation-state but are the ancestors of Rapa Nui people. These cases show the unexpected effects of multiculturalism, as indigenous leaders take advantage of the open spaces of multicultural politics to raise their own demands, boost their processes of historical construction and identity, and dispute their patrimonial rights before the state and science.

Final Words

This article has discussed the relations between archaeologists and indigenous peoples in Chile within the changing contexts of colonialism, nationalism, and multiculturalism. The history of archaeology shows that the reproduction of colonial denial of indigenous rights has been a central factor in conflicts between archaeologists and indigenous peoples. However, there has been a significant advance in the last two decades in the participation of indigenous people in archaeological work and different approaches to this. On one hand, an ethnographic turn in archaeology is identified as well as the development of public or heritage archaeology; then again there are experiences with different degrees of indigenous involvement. While some projects materialize indigenous participation mainly in activities of diffusion, public relations, and the management of archaeology, others are associated with collaborative proposals that promote a greater reflexivity and disciplinary decolonization. Although archaeologies committed to decolonization are still marginal in Chilean archaeology, the experiences discussed in this essay highlight alternative paths for archaeology with, by, and for indigenous peoples.

Finally, although the internal heterogeneity of the Aymara, Atacameño, Mapuche, and Rapa Nui communities was not addressed in this study, future research is expected to account for intra- and intercommunity social and political complexity; this will undoubtedly affect an understanding of its bonds with archaeology. This will also be enriched and made more complex with the analysis of Quechua, Kolla, Diaguita, Kawésqar, and Yagán cases.

Chile, Historical Archaeology of

Flora Vilches and Daniella Jofré
Departamento de Antropología, FACSO, Universidad de Chile, Santiago, Chile

Introduction

Historical archaeology in Chile is substantially less developed than archaeology that studies the pre-Hispanic past, as it is also the case in the rest of South America (Funari 1997; Jamieson 2005). Since the last decade of the twentieth century, however, studies have multiplied leading to a

diversification of the topics under discussion, often times accompanied by more structured theoretical frameworks (Funari et al. 2009).

The VII National Congress of Chilean Archaeology, held in 1977, is recognized to be the first moment when ethnohistorians, archaeologists of the historical period, and physical anthropologists came together to present the results of their lines of work. This first symposium on historical archaeology, focusing on colonial ethnohistory and archaeology, emerged as part of a series of symposia devoted to a range of topics set within the prehistory of Chile (Bittman 1977). It was organized in response to an appeal by historians like Casassas (1976), who had drawn attention to the need for interdisciplinary work between archaeologists and historians. However, the works published in the symposium were no more than the results of independent disciplinary studies and lacked collaborative discussion and/or methodology between the disciplines, which in the best of cases was restricted to a declaration of intent. This has been the tonic of the sporadic and, to a large degree, fortuitous or circumstantial studies carried out up and down the country since the early 1970s, which have continued to proliferate in the twenty-first century (Gomez 2013).

In parallel with the course of archaeological research, legislation has also done little to promote the study – or even the mere protection – of the vestiges of the more recent past. The law on national monuments, dating from 1970, clearly indicates that both "places, ruins, constructions or objects of a historical or artistic character" and "the burials, cemeteries or other remains of aboriginal peoples" are national monuments under the guardianship and protection of the state (Title I, Art. 1, Law 17.288 1970). However it also distinguishes between an archaeological monument and an historical monument, while the former is state property "by the sole action of the law" (Title V, Art. 21, Law 17.288 1970), the latter must be declared as such "by supreme decree" and as a function of its historical quality and interest (Title III, Art. 9, Law 17.288 1970). Consequently, historical remains exist in a gray space, and the lack of a clear definition increases their fragility, putting them at permanent risk. This situation became even more pronounced with the introduction of the Law on the General Bases of the Environment, in the mid-1990s (Law 19.300 1994), which paved the way for the development of contract archaeology.

The development of infrastructure in urban and rural contexts has uncovered large numbers of historical data, which have demanded the ever-growing specification of methodologies and conceptual (including legal) definitions by archaeologists. Given the high demand and urgency of contract archaeology, the study of the historic material involved has resulted in sporadic specific studies, with little follow-up into more structured themes, let alone archaeological problems. In addition, the majority of the studies carried out in the framework of contract archaeology do not get published. They remain as technical reports or manuscripts with little circulation, thus weakening the possibility of their involvement in local disciplinary debate, let alone in global discussion. Other contributions not framed within contract archaeology, such as undergraduate or graduate theses, are also left unpublished (e.g., Botto 1989; Cáceres 2011; Pinto 1976). It must be noted, however, that in the last 15 years, the writing of undergraduate theses on diverse topics within historical archaeology has increased. This trend might be due to the fact that some anthropology departments have also included historical archaeology as a subject in their curricula, sparking the interest of younger generations in the post-Hispanic past.

Substantive Themes/Current Debates

Although there are no major archaeological research programs for the historical period in Chile, certain topics can be distinguished as problematic themes, which have taken shape and developed **over time**.

1. The *colonial period*. One topic that has emerged following the emergence of historical archaeology in Chile is the colonial era, which spans the three centuries from the first Spanish contact with the indigenous peoples through

to the formation of the Republic (sixteenth to nineteenth centuries). This era has mainly been treated descriptively and as a strictly chronological slot, rather than as a complex cultural process involving social, economic, and political issues. In general, studies revolve around particular architectural structures (e.g., churches, towns, fortifications), exploitable resources (ores and minerals), conspicuous objects (earthenware, glazed ceramics), and bioanthropological remains, with scant efforts to link them. This phenomenon is observed equally in the north of the country (e.g., Chacón 1969; Alcaide 1983; Núñez 1984; Hidalgo and Focacci 1986; Sanhueza 1991; Chacama 2010; Vilches and Sanhueza 2010), the central zone (e.g., Reyes et al. 1998; Sanhueza et al. 2004b; Prado and Barrientos 2011; Prado et al. 2015), the southern zone (e.g., Gordon 1978; Mera et al. 2004), the Juan Fernández archipelago (Orellana 1975), the extreme south (e. g, Massone 1978; Ortiz 1970, 1971; Reyes et al. 2004), and in Antarctica (Stehberg and Cabeza 1987; Stehberg 2003). In recent years, efforts have aimed to integrate the colonial era into diachronic regional studies extending forward from pre-Hispanic times to the Republic. This has led archaeologists to formulate more profound questions about sociohistorical processes, with emphasis on the continuity and change of cultural practices. There are two particularly interesting examples that we will refer to.

In the Tarapacá Region in the north, systematic ethnohistorical work has enabled a better and more complete understanding of the archaeological record of the fifteenth to eighteenth centuries and especially of the Spanish contact with the indigenous peoples in the area (Urbina 2018; Urbina and Uribe 2016). This synthetic work has been fed by more specific archaeological studies based on architectural patterns (Urbina et al. 2018) and metalworking technology (Zori and Tropper 2010) from the formative period to the early colonial. Also in Tarapacá, the work of Santoro and his team seeks to further understand the region from when it was first peopled until the present, with emphasis on socio-environmental changes (Núñez et al. 2010; Santoro et al. 2017).

In the south, in the Los Ríos Region, we find a unique example of a fully-fledged research program, centered on the city of Valdivia and its jurisdiction between the sixteenth and nineteenth centuries. The ample territorial perspective of this research has helped to understand the variability of settlements as well as the interconnections between them and thereby the richness and nuances of an intercultural context. Different types of settlements such as residential, administrative, defensive, and missionary have been studied, including ceramic types and architectural traits belonging to both indigenous and European traditions (Brooks et al. 2019; Mera et al. 2018; Urbina et al. 2012; Urbina and Adán 2014) (Fig. 1). There are also a few works that extend the chronological interpretation of material culture from the city of Valdivia up to the twentieth century (Munita and Mera 2016).

A further example is the colonial fortress known as Castillo de Niebla, today a state-funded site museum, and its strategic location within a complex exchange system set up at the mouth of the Valdivia River (Lema 2017; Urbina 2018). Of particular interest have been systematic surveys, including underwater archaeology in 2009 (Hermosilla and Bahamondes 2010), which revealed a great quantity of socially significant materials such as Mapuche and Hispanic pottery. Its architectural restoration contributed to study contact materials from 1544, between the first Spanish settlement and the Ainil population that dwelled along the Huayrona stream. Currently, the museum has engaged the local community of Niebla to disseminate material collections within its historical landscape and cultural heritage.

Other research examples of overarching studies that span along pre-Hispanic and post-Hispanic periods of time and across different territories have focused on the Mapuche from

Chile, Historical Archaeology of, Fig. 1 Excavation at San Pedro de Alcántara Castle, Mancera Island. (Photographic Archive, Dirección Museológica, Universidad Austral de Chile. Photo: © Simón Urbina A., ECOMUSEO Proyect Mancera, 2014)

the Bío Bío and Araucanía regions, mainly in terms of environmental change and traditional mound construction, as well as cultural contact and resistance strategies (e.g., Dillehay and Saavedra 2017; Gordon 2011; Sauer 2015).

This new form of problematizing the colonial period implies the use of theoretical frameworks that question the presence and *modus operandi* of the colonial power and the modes of resistance to it, as well as the nuances of interethnic relationships. Methodologically, it achieves better interaction between ethnohistorical and archaeological work, allowing for more integrated and creative readings of the phenomena under study.

2. *Urbanism*. Various development projects in the capital city of Santiago, in the Metropolitan region, have helped to understand its distinctive urbanization process, with archaeological projects in iconic locations such as Santa Lucía, Casa Colorada, Teatro Municipal, Plaza de la Ciudadanía, Palacio de la Real Aduana, ex-Hotel City, Palacio Pereira, Casas de lo Matta, and ex-Congreso Nacional, among others. Particularly relevant has been the ongoing project of the subway construction that started in 1969 and, since 2003, has added several metro lines to interconnect the city. This project has helped to map Santiago since its original foundation by the Spaniard Pedro de Valdivia in 1541, complementing it with historical documentation for public works such as roads, sewers, canals, and bridges (e.g., Morel and Pinto 1975; Reyes et al. 1998; Sanhueza et al. 2004b) (Fig. 2).

Restoration projects at the heart of Santiago have also contributed to such an endeavor by uncovering pre-Hispanic occupations and colonial construction techniques along with elite burials in the Metropolitan Cathedral and the Santo Domingo and the San Francisco temples, versus non-elite burials in the cemeteries of La Pampilla from the San Juan de Dios Hospital (e.g., Jorquera and Soto 2016;

Chile, Historical Archaeology of, Fig. 2 Pique Acceso Arturo Prat, Line 3 subway construction, Santiago. (Republican "huevillo" or pebble floor in the intersection of Arturo Prat and Avenida Libertador Bernardo O'Higgins. Photo: Verónica Reyes, Archaeological Compensation Stage Excavation for Metro, 2015)

Medina and Pinto 1980; Prado et al. 2000; Rozas et al. 2014; Westfall and Cáceres 2011). Other works focusing on human remains and funerary practices from colonial and Republican times were undertaken in parishes and churches within the Metropolitan region, specifically in Colina, and in Rancagua, located south in the O'Higgins region (Rodríguez et al. 2004; Sanhueza et al. 2004b).

At the Valparaíso seaport, despite the urban context of development, research has not been systematic in understanding the original configuration and has been forced to respond "on demand" to contract archaeology, resulting in an eclectic methodology that integrates historical documents and unique techniques to classify a range of materials. For instance, the excavation of an underground parking space below Plaza Sotomayor partially uncovered the Stock Exchange building as well as part of the original pier which reused wood from The Esmeralda, an iconic national ship captured by Lord Cochrane in 1825 (Didier and Riveros 2004). Other findings derived from ship wreckages in the Valparaíso bay, such as the Wager from 1855 and the Potsdam in 1891, as well as underwater surveys for new pier development which have helped to interpret the complexities of the maritime exchange system (Carabias 2015a, b).

3. *Mining and technology*. Study of the mining of metal and other minerals is another recurrent issue in the practice of historical archaeology in Chile. In general, it has been carried out in the north of the country, covering a broad time spectrum with studies that range from completely descriptive to the inquiry of more profound questions (Salazar and Vilches 2014). It is perhaps in the Republican period (nineteenth and twentieth centuries) that we can discern a clear intention to pursue a proper topic of research, that is, industrial capitalism

as a global phenomenon and its local manifestations.

The majority of works focus on the social organization of single settlements devoted to the exploitation of diverse ores, mainly metals (e.g., Arancibia et al. 2012; García-Albarido et al. 2010; Rivera and Lorca 2007) but also guano and nitrate (e.g., Alcaide 1983; Méndez-Quirós and Sánchez 2012; Bittman and Alcaide 1984). Unlike the aforementioned studies, the work on the nitrate industry has also been approached from a regional perspective in order to understand the settlement patterns and more nuanced social internal logics of the nitrate cycle (e.g., Rees et al. 2010; Vilches et al. 2008, 2013; Kalazich 2018) (Fig. 3). The same studies have given rise to investigations into subsidiary industries dependent on major industrial exploitations, such as cattle trafficking and salt or sulfur mining, which help to explain the wider capitalist context supported by large-scale mining and local adaptations to a global phenomenon (e.g., Vilches et al. 2014; Vilches and Morales 2017). Sulfur mining, however, was recently studied in its own right in the region of Arica and Parinacota. Interestingly, this study puts mining into perspective within the context of nation building in a frontier area (Angelo 2018).

Although not directly related to mining, we must mention the work led by Miguel Fuentes in Rapa Nui, which deals with the sheep industry as another form of extractive industrialization (Fuentes 2013; Fuentes and Cristino 2010; Cristino and Fuentes 2011; Fuentes 2013; Fuentes and Cristino 2010). Aside from the interest in understanding the varied facets of industrial capitalism, this work shares its methodological component with those on mining. While all of them combine the use of historical documents, oral history, and material culture, only some succeed in a real imbrication of these three sources and not a mere juxtaposition of them. Interestingly, most of these works have also discussed issues relating to the "heritagization" processes that have affected the historical materiality of industrial capitalism. They demonstrate the presence of tensions between the state, local communities, and

Chile, Historical Archaeology of, Fig. 3 Luisis 1 Camp, located at the outskirts of the Luisis Nitrate Ofiice, Cantón Central, Antofagasta Region. (Photo: Flora Vilches, FONDECYT Project 1080542)

foreign capital as to the definition of heritage and who owns it (e.g., Fuentes 2013; Rivera and Lorca 2010; Vilches et al. 2015).

Cultural change has also been studied through the lens of technologies other than mining, in terms of what artifacts can say about the society that produced them. European adaptations to native technologies have been looked at in the local production of indigenous boats, rafts, dugouts, and canoes (e.g., Carabias et al. 2010; Hajduk 1987; Legoupil et al. 2011; Lira et al. 2015; Lira 2018), as well as in traditional fishing techniques such as the corrals (Álvarez et al. 2008). In this regard, new approaches have studied continuities and discontinuities between precontact and postcontact materials, as well as the use of different technologies in both Mapuche and Hispanic assemblages (Munita et al. 2018).

4. *Political Violence and Local Communities*. Despite the difficulties in analyzing Chile's dictatorial past, the repressive and violent practices of the military regime have not been left out of archaeological research and scope (Fuenzalida 2017) (Fig. 4). With the return of democracy, and of community participation, its technical expertise has helped to complement testimonies, documents, and material findings into a coherent narrative of the past, primarily centered in the metropolitan area of Chile. In this sense, interdisciplinary research has also contributed to the critical construction of the recent past, especially with physical anthropology and conservation within human rights' legislation, for the recuperation of remains coming from human rights violation that are involved in judicial cases (e.g., Cáceres and Jensen 2007; Carrasco et al. 2003, 2004; San Francisco et al. 2010).

Chile, Historical Archaeology of, Fig. 4 Archaeological works undertaken at the Londres 38 mezzanine, a clandestine torture and disappearance centre which has been claimed by a community network as a site of memory. (Photo: Nicole Fuenzalida & Andrea Martínez, Archaeological and Forensic Study in Londres 38 for Mazo Arquitectos Ltda, 2019)

This new line of work has gradually contributed toward restoring a general sense of justice, allowing for the emergence of a recently formed network of sites of memory that collectively developed general guidelines (CARCH and CNCR 2017). The social, technical, and even legal role that archaeology has played for "sites of memory" has helped to reconstruct, at some level, the micro-history of both urban and rural areas, making space for "new social archaeologies" engaged with different publics as people get more exposed to and involved with the material findings (Carrión et al. 2015). The impact of this line of applied archaeology in local communities can be quite decisive (e. g., Jofré 2012). An example is the information drawn from the seasonal occupations and historical cemeteries in indigenous territories excavated for the construction of the Ralco Hydroelectric Plant in 1999 (Westfall 1998) and of the Temuco Bypass in 2001 (Paredes 2015). Note that the 1998 Congress of Anthropology in Temuco was the first time that issues about restitution, repatriation, and reburial on native grounds were publicly expressed by Mapuche representatives to the academic community (Ayala 2018), an issue that has continued to echo historical demands. In this sense, the Chilean state has also operated as a violent agent by denying indigenous interpretations of the past and refusing to recognize their rights over traditional native territories, material culture, and even aboriginal bodies, some of which continue to be displayed at museums' exhibits.

5. *The contemporary world*. This topic covers studies of archaeology in and of the present, that is, of contemporary society in and of itself, moving the discipline away from only which is ruined and has ceased to function (Harrison 2011). Although there has been little theoretical discussion among Chilean archaeologists about this "subdiscipline" of archaeology, in strictly chronological terms, it falls within the realm of the post-Hispanic era and can thus be considered historical archaeology.

A couple of works can be grouped under this subject, despite the fact that they come from different directions. On the one hand, Angelo (2017) explicitly engages in the current academic global discussion while studying a partially ruined house from the late nineteenth century to the early twentieth century in the city of Arica. The understanding of the production of social space throughout time in that settlement includes the processes of gentrification and of heritage-making that are affecting the area today. Additionally, a handful of studies on industrial mining (Theme 2) also delve into the life of archaeological materiality once it enters contemporary contexts of exhibition and heritage management (Rivera et al. 2015; Vilches et al. 2015).

On the other hand, a number of works produced by Gallardo back in the 1990s (Gallardo 2018) address varied objects such as a museum exhibition of pre-Columbian artifacts, the artwork of a contemporary visual artist, and a shopping mall. Gallardo's practice stems from theoretical discussion on postmodernism in general but which is also indebted to the archaeology of modern material culture that arose in the 1970s (e.g., Gould and Schiffer 1981). In that respect, many of his observations seem to anticipate the more complex discussion on the archaeology of present times that will fully develop in the twenty-first century (e.g., Harrison 2011).

Final Remarks/Future Directions

The practice of historical archaeology in Chile has developed rapidly in the last couple of decades, to a great extent, due to the rise of contract archaeology. The abundance of newly revealed historic contexts and materials, however, has not been necessarily coupled with a more acute definition of substantive themes of study. The topics that can be identified are uneven in terms of depth and continuity over time since only a few studies aim to purposefully understand the social processes underlying the material findings. This situation appears to be changing as the very accumulation

of historical data is prompting archaeologists to pose new questions by piecing together previously sporadic information. Additionally, the development of specific methodologies to analyze various kinds of materials (e.g., glass, high-temperature earthenware) has reached a level of maturity that may facilitate pursuing certain lines of inquiry. It is worth noting a systematic effort for cataloguing and contextualizing the production of ceramics and other objects uncovered in different development projects from Santiago and Rancagua, which has recently published two volumes (Brooks et al. 2019; Henríquez et al. 2013, 2016). Likewise, the better imbrication between documentary sources and archaeological materials proves to be a growing trend among archaeologists who either manage both sources on their own or work closely with experts from other fields.

A need for a firmer theoretical discussion on the very definition, objects, limits, and other issues that concern historical archaeology is also a must in the years to come. This may or may not follow international trends but should be able to engage critically in global discussion. Something to look at is the fact that the last decade has witnessed an interesting shift in the way archaeologists have chosen to frame their work on historical material as part of national archaeology conferences. From the 1970s to the first decade of the twenty-first century, symposia on historical archaeology were limited to one session at each conference defined strictly on chronological terms (postconquest), and they grouped studies from a wide range of topics. Since 2012, nonetheless, we can observe a broader selection of sessions in which archaeologists present papers dealing with the more recent past, sometimes sharing themes with studies on prehistoric materials and some others on their own. That is the case of sessions on "archaeology and politics" or "public archaeology" that unite works on both prehistoric and historic archaeology, while we also find sessions devoted solely to the archaeology of "political violence" or "capitalism in the southern cone" (Actas 2012, 2015; Resúmenes 2018). This marks a timid yet powerful statement of national historical archaeology that proves to be evolving into dealing with proper problems and themes rather than remaining trapped by chronology.

C

Chile's World Archaeological Heritage and Its Management

Mario A. Rivera
Programa Identidad del Fin del Mundo,
Universidad de Magallanes, Punta Arenas, Chile

Introduction

Chile's archaeological heritage as we envision it today is based mainly on the existence of aboriginal communities within the national territory; the significance, since the sixteenth century, of the occurrence of these societies and native cultures; and their historic importance in the development of the national society as well as its identity. The emphasis in the national character that played the increasing interest in rescuing the sources and antiquities that were part of the national heritage was crucial as it was the cultural and scientific European influence, especially from France and Germany that arrived in Chile during the nineteenth century.

Chile's National Council of Monuments by means of Legislative Act 17288, article 21, considers as archaeological monuments all the ruins,

sites, and anthro-archaeological artifacts that are located in the surface and below of the land covers by the national territory. Officially, NCM recognizes in its web page a total of 21 main archaeological sites as of October 2008. However, the richness of archaeological material in Chile is far more numerous. In fact, only in Northern Chile, the landscape that is characterized by the dryness of the Atacama Desert, archaeologists have recorded thousands of sites with excellent conditions of preservation, due to the environmental conditions of the desert. This fact has allowed archaeologists to obtain a relatively complete 10,000-year chronological sequence that encompasses sites containing remains of hunters and gathering cultures, the Chinchorro cultural complex notable for the mortuary treatment that involves the world earliest mummies, and the typical Andean cultures during formative and later stages, where Tiwanaku and Inka influences are most typical. The oases of the Atacama Desert also played an important role in preserving past human occupations. Remarkable are the two examples of these oases, Pica and San Pedro Atacama, where, preceded by early hunting stages, relicts of Andean cultural development are found. Here the most typical pre-Hispanic features are the Tiwanaku and Inka influences that acted upon the regional San Pedro culture. Here, the late periods are characterized by the emergence of defensive settlements called pukaras stretching a line stretching from east to west. Additionally, this area also views the emergence of village life during formative times.

To the south, the semiarid mid-north of Chile, ancient hunting societies yielded to formative developments around the time of Christ. To the classic site of Quereo, newly discovered paleo-American hunters sites include Quebrada Santa Julia and Membrillo (Jackson and Mendez 2008). Archaic developments are represented by Huentelauquen complex characterized by cogged stones or lithics with geometric shape. Formative developments begin with El Molle complex followed by Las Animas phase of the Diaguita culture that permeates the regional development all the way up to the Inka incursion in the area.

Within Central Chile further south, important paleo-American sites were recorded at Tagua Tagua and Monte Verde. Thereafter, archaic and formative developments occurred in close connection with Chile's mid-north region. Later, the Araucanian regional cultures developed from the Andean Formative ceramic traditions.

Further south, two different types of adaptation occurred in the Patagonian settings. In the continental area, hunter societies developed, while in the coastal environments of the Pacific, the main adaptive mechanism was fishing and sea hunting. Prehistoric development started with paleo-American sites from about 10,000 years ago up to present-day aboriginal people surviving in the area.

Definition

The Archaeological Patrimony

If we are to list Chile's most important archaeological patrimony, the following could be the most representative.

In Northern Chile, perhaps the most outstanding corresponds to the Chinchorro culture. Although it extends from about coastal Ilo in Southern Peru to nearby Antofagasta in Chile, the main archaeological sites are located in the vicinity of Arica city, at Chinchorro type site, Camarones valley, and around Iquique. Burial sites containing the world earliest mummies dated from about 6000–1100 BC were located at Morro 1 and Playa Miller 8 in Arica. To the south, other important sites are Camarones 15 and Patillos.

Human embalmed bodies that represent the Chinchorro culture have an inner reinforcement structure of bones, reeds, sticks, and clay and an external surface of skin and manganese paint. Facial features were reconstructed or insinuated, with a short wig added to the head. Additionally, some bodies were also stuffed, and incisions were made to the body removing internal organs. Then, grasses and feathers were used to fill in the thoracic cavity in order to recover the lost volume. Once reshape, the bodies were painted bright red, green, or black (Figs. 1 and 2). Wigs and teeth

Chile's World Archaeological Heritage and Its Management, Fig. 2 Chinchorro mummified head from Patillos site (© Mario A. Rivera)

implants were used to ornament the head, and facial features were modeled (Arriaza 1995; Rivera 1995).

Further south, it is important to mention the early village complex that developed in the midst of the Atacama Desert during formative times. Among these are important to mention Guatacondo and Ramaditas, in the Guatacondo Valley; Tulor (Fig. 3), Calar, Tulan, Solor, and Vilama in the San Pedro area; and Chiu Chiu in the confluence of the Salado and Loa rivers. There, cluster types of settlements represent a good testimony of how man was coping with the harsh environment. In San Pedro Atacama, two later sites are also of importance, Pukara Quitor (Fig. 4) and the Inka site of Catarpe. Additionally, it has been recently reported the site of San Ramon in the coastal area of Taltal, south of Antofagasta. There, it has been claimed the 12,000-year-old iron oxide mine is believed to be the oldest mine in America (Salazar et al. 2009).

Vast areas covering designs visible from long distance and known as geoglyphs are important to mention. Thousands of them are distributed throughout the desert perhaps as indicators of ancient routes. The most important concentration is located around Pintados (Fig. 5 and 6) and further south in the Quillagua area.

In Chile semiarid zone, the impressive paleo-American sites of Quereo and Quebrada Santa Julia contain excellent stratigraphic and contextual data on the issue of early man in America. Other sites that provided a complete sequence from about 7000 years to present time is the rockshelter of San Pedro Viejo de Pichasca, located inland from Ovalle city. El Encanto, also near Ovalle, is a well-preserved site with hundreds of petroglyphs and archaeological remains from El Molle culture. In the vicinity of Copiapo, two important Inka sites are La Puerta and the metallurgical center of Vina del Cerro that has undergone an extensive conservation program. Further north, at the mining city of El Salvador, there are the remains of a turquoise mine of Inka origin still in place under the care of Museo Regional.

Stretching from north to south is the old Qapaq Nan or Inka Road. Sections of it have been subject of thoroughly investigations, and it is now part of a major cooperative Andean program sponsored by UNESCO (Niemeyer and Rivera 1983; Santoro 1983; Berenguer and Caceres 2008).

Central Chile, particularly Santiago, and its vicinity contain mainly late sites of which the

Chile's World Archaeological Heritage and Its Management, Fig. 3 Tulor village site located in San Pedro Atacama area (© Mario A. Rivera)

Chile's World Archaeological Heritage and Its Management, Fig. 4 Pukara Quitor, San Pedro Atacama area (© Mario A. Rivera)

fortified outposts of Cerro Chena and La Compania are significant. The former an Inka site while the latter, of an earlier development probably belonging to Promaucae origin later occupied by the Inkas. An outstanding feature is the mummy of Cerro El Plomo. This is a child body, probably 8–9 years old that was sacrificed by the Inkas at the summit of Cerro El Plomo inland from Santiago at 5,430-m altitude. There, the Inka sanctuary kept the body frozen until it was discovered in 1954. It is in perfect shape with all garments and dresses still intact on display at the Museo Nacional Historia Natural in Santiago (Fig. 7).

Chile's World Archaeological Heritage and Its Management, Fig. 6 Geoglyphs of Tiliviche, Pampa del Tamarugal (© Mario A. Rivera)

South of Santiago, Tagua Tagua is the best recorded paleo-American site with clear evidence of mastodon remains associated to human activities. Further south, the Araucanian area is still poorly investigated, despite the fact that living groups of Mapuche people play a crucial role even today. Perhaps the most important sites are Los Catalanes Cave and Pucon, mainly because of their stratigraphy records. Puerto Montt is the site of Monte Verde where evidence of Pleistocene fauna had been linked to human activities at least by 11,000 BCE, if not earlier (Dillehay and Collins 1988).

In Patagonia as well as all the extreme south of Chile, a widely spread rock art known as Patagonian Style is found from General Carrera Lake in Chile Chico to Magellan Strait. It is believed is the oldest in South America as it is characterized by designs of red or black hands done its negative painting. Other motifs are guanaco figures and highly complex geometric designs. Due to the isolation of this southern land, the style remained

Chile's World Archaeological Heritage and Its Management, Fig. 7 Frozen body of child, Inka sanctuary of Cerro El Plomo, Santiago area (©Adriana Goni)

unknown until recently and in excellent conditions. At Los Toldos rockshelter in Argentinean Patagonia, they have been dated at 10,000 years. Also in Patagonia, cave sites such as Fell, Palli Aike, and Eberhardt related to early hunters and gatherers, associated to Pleistocene fauna, have been found in connection with human activity. They are outstanding examples that have been in the literature since the 1890s, with important research done by renowned figures such as Junius Bird and the New York American Museum of Natural History and Joseph and Annette Emperaire and the French Archaeological Mission to Patagonia.

Key Issues/Current Debates/Future Directions/Examples

Management of the Archaeological Patrimony

Generally speaking, conservation and management of archaeological sites in Chile are poor. Corporacion Nacional Forestal, the equivalent to National Park Service, is the official institution responsible for the management of sites. However, only a handful sites are actually under their supervision, most notably the geoglyphs of Pintados and the site of Tulor, in arrangement with the local Atacameno community of Coyo.

Responsibility of the archaeological patrimony is also a problem because of a lack of clear definition on accountability for managing, storing, and preservation both of archaeological sites and collections. Several institutions, from Chile's Departments of Education and Cultural Affairs to Chile's Departments of Agriculture and Land, are all concerned with issues related to archaeological patrimony. Aside from these facts, there is a suite of instances for managing archaeological collections. Museums' responsibility is varied, whether they are state or municipal museums, private or university ones.

Two other factors are against archaeological patrimony. Contract archaeology programs are done in response to contracting companies' goals that plan to intervene the landscape. A second situation that destroyed hundreds of archaeological sites in the Atacama Desert was the recent versions of the Dakar International Rally, originally the Paris-Dakar rally with participation of hundreds of vehicles and enterprises from all over the world. In the last three years, several stages took place in the Atacama Desert leaving a somber panorama of destruction in the sandy pristine landscape. A recent report from Consejo Monumentos Nacionales reveals that 283 of the 556 sites were affected by the rally with an almost 50% of deterioration.

San Pedro Atacama is probably the only place in Chile where native organizations have claimed their right to manage archaeological sites. However, internal disputes do not allow a clear-cut outcome up to date. In any event, Museo Arqueologico Gustavo Le Paige in San Pedro has done an excellent job in conserving and managing the archaeological collections from the area. Corporacion Nacional Forestal manages the site of San Pedro Viejo Pichasca mainly because the archaeological site is part of the national paleontological reserve.

In Arica, conservation and display, as well as research of Chinchorro, is in care of Universidad Tarapaca and its Azapa Museum of Archaeology. Recently, they have added a new building containing excellent displays and storage facilities, especially designed for the Chinchorro remains. A new site museum located in downtown Arica on Colon street displays burials of the Chinchorro culture in situ.

In some instances, local institutions also manage archaeological sites. This is the case of cities like Iquique, Tocopilla, Taltal, and Ovalle, among others. In this last city, the city has taken control of El Encanto archaeological area transforming it in a city park.

There are several museums in Santiago where archaeological collections from Chilean territory are stored. The oldest and most important museum is Museo Nacional Historia Natural where reference collections from the entire country are kept. Additionally, the museum also stores collections from the most relevant field works done in Chile at least until 1980s. Museo Historico Nacional also contains some archaeological collections. Both museums are part of the Direccion de Bibliotecas, Archivos y Museos, an administrative organization that is under the Secretary of Education. Additionally, state museums are located in all the major cities along the country being those in La Serena, Antofagasta, and Valparaiso the most important. Private museums in Santiago are also important. The best known is perhaps Museo Chileno Arte Precolombino. It was founded in 1981, and it functions as a joint venture between Fundacion Familia Larrain Echenique and the city of Santiago. Other private museums managing archaeological collections are Museo Arqueologico de Santiago, founded in 1994 by Fundacion Cultural Plaza Mulato Gil. In addition, two museums belonging to private organizations are located nearby Santiago, Museo Andino founded by Fundacion Claro Vial in 2006 and Museo de Colchagua that opened in 1995 by Fundacion Cardoen.

In Valdivia, Universidad Austral de Chile takes care of Museo Historico y Antropologico Mauricio Van de Maele. In Patagonia and extreme Southern Chile, managing archaeological sites and collections has been in the hands of a couple of museums, namely, Museo de la Patagonia and Museo Salesiano. A third institution, Universidad de Magallanes, and its Museo del Recuerdo managed by Instituto de la Patagonia have being pursuing intense lab work as well as research. Ultimately, conservation efforts as well as display of collections are all regulated by National Council of Monuments and the National Restoration Center.

China: Cultural Heritage Management

Junjie Su[1] and Hong Chen[2]

Introduction

China owns a rich variety of cultural heritage, including not only tangible monuments, historic buildings, and artifacts but also various intangible traditional cultures. Nowadays China plays a significant role in the world in nominating, applying for, and protecting World Heritage and Intangible Cultural Heritage (hereafter as ICH) within the UNESCO program. Domestically, China recognizes the crucial role of cultural heritage in its national political, cultural, economic, and social constructions. It is therefore an important issue to understand how cultural heritage is conceptualized, managed, protected, and used in China as it strives to promote its economic modernization as well as cultural rejuvenation.

This entry aims to illustrate characteristics, issues, and reforms of the cultural heritage management system in China. Section "Discourses and Concepts" provides background and historical context of Chinese cultural heritage management. This section specifically illustrates how the concept of cultural relic evolved into present cultural heritage and, consequently, how the official discourse of cultural heritage developed accordingly. Section "The Management System: Characteristics" delineates the characteristics of Chinese cultural heritage management system. In China, the majority of cultural heritage is administrated as a nonprofit enterprise by the government with a hierarchical localized management measure. As this system was formed during a unique historical, economic, and cultural situation in China, several issues emerged which are related to the practical management problems in present China, such as the institutional causes and managerial deficiencies. These issues, as well as the practical management problems, are investigated in section "The Management System: Issues". Afterward, the reforms that Chinese heritage authorities have taken in heritage management are described in section "The Management System: Reforms". Along with the advancement of Chinese economic and social reform, this section uses cases to display how different heritage sectors experiment reforms in both marketization and non-marketization ways with participation of the social actors. Finally, section "The Management of Intangible Cultural Heritage" illustrates a new component of Chinese cultural heritage management system, the management of ICH, so as to complete the comprehensive system of Chinese cultural heritage management.

Discourses and Concepts

Heritage is currently regarded as not only a discourse (Hall 2001) but also a cultural practice (Smith 2006). The official discourse of heritage in China is central to the official cultural practice in China. This section provides a historical background of the transformation of Chinese heritage discourse, as well as the related concepts, which will also form the context to understand the practice of Chinese cultural heritage management in late sections.

Concept of Cultural Relic in Ancient China

The term cultural relic, or "Wen Wu" (文物) in Chinese, is the most significant concept underlying the discourse of cultural heritage in China. The term cultural relic firstly appeared in book *Zuo zhuan* (the Commentary of Zuo) in the early Warring States Period (B.C. 475–B.C. 221) and the meaning concerns sacrificial vessels (such as bronzes and steles) used in the imperial ritual, etiquettes, and rules (Li 2002, 1). The emergence of epigraphy in the Song Dynasty (A.D. 960–A.D. 1279) and textology and the collection of antiques in the Ming (A.D. 1368–A.D. 1644) and Qing (A.D. 1644–A.D.1912) Dynasties extended the concept of cultural relic to include not only

imperial utensils but also many kinds of valuable antiques and ancient artworks in private collections (2). At that time, however, only a small amount of moveable cultural heritage was included in the concept of cultural relic.

Management of Cultural Relics Before 1949

The connotation and extension of cultural relic was transformed along with the establishment of the first group of museums in China (e.g., in Shanghai in 1868 and in Nantong, Jiangsu, in 1905) and the inaugural archaeological excavations in Henan Province and Beijing in the 1920s (Gu and Yuan 2005). The concept of cultural relic was extended to a larger scope to incorporate immoveable archaeological sites, monuments, and historic buildings.

Government management of cultural relics was initiated in this period. The first cultural heritage regulation in China, *Antiques Preservation Law*, was issued by the Republican Government in 1930. As a result, in addition to moveable cultural relics, cultural heritage in the form of historic buildings and archaeological sites were included in governmental administration.

Management of Cultural Relics from 1949 to 1985

While the term cultural relic has been well maintained in government management system since the founding of the People's Republic of China in 1949, the connotation and extension of this concept has underwent expansion. The official stipulation of cultural relics was narrated first in *Provisional Regulations on the Protection and Administration of Cultural Relics* (full text see http://www.china.com.cn/cpc/2011-04/15/content_22370386.htm, retrieved on 8 December 2017) in 1961 and then written in the first cultural heritage law in China, *Law of the People's Republic of China on Protection of Cultural Relics* (full text see http://www.sach.gov.cn/art/2015/6/1/art_1034_121351.html, retrieved on 8 December 2017) (the LPCR hereafter). The LPCR was initially issued in 1982 and then revised in 1991, 2002, 2007, 2013, 2015, and 2017. Although the definition of cultural relic is not articulated in the LPCR, the extension of it remains more or less constant from the *Provisional Regulations* in 1961 to the LPCR in 2017.

Several characteristics of the concept cultural relic can be discerned by reviewing these governmental documents. First of all, cultural relic emphasizes the materiality of heritage. Cultural relics concern two categories: the first is immovable cultural relics, such as sites and monuments; buildings, structures, and murals; and historic towns or villages. The second is moveable cultural relics, such as artworks and crafts; documents, manuscripts, and books and objects. Another characteristic of the concept cultural relic is that the historical, artistic, and scientific values are underscored in the official authentication process. Based on the assessment of these values, immovable cultural relics are classified as national key protection units, provincial protection units, and municipal/county protection units. Similarly, moveable cultural relics are classified as valuable cultural relics (further classified as grade one, grade two, and grade three) and ordinary cultural relics (Li 2002).

Management of Cultural Heritage After 1985

Chinese government's protection of cultural relics was severely interrupted during the Cultural Revolution from 1966 to 1976. (This is a social-political movement activated by then Chinese Chairman Mao Zedong to strengthen the communist ideology by purging remnants of capitalist and many traditional Chinese cultures and cultural relics, denouncing them as "bad cultures.") After the Open Policy reform initiated by Deng Xiaoping in 1978, China's national agenda shifted from ideological struggle to economic modernization. As a result, cultural heritage is reconsidered as beneficial to China's nationalism, socialism, and modernization (Sofield and Li 1998). Along with China's Open Policy, international heritage discourses were introduced into China. The most significant event is China's ratification of the *World Heritage Convention* in 1985, while the concept of "cultural heritage" was imported into China. Nevertheless, the term cultural heritage has not been as common as cultural relics until 2005 when the term cultural

heritage was written in Chinese governmental documents for the first time.

2005 is a crucial year as two important concepts, namely, cultural heritage and ICH, formally appeared in the governmental documents for the first time. In the *Notification of the State Council on Strengthening the Protection of Cultural Heritage* (full text see http://www.gov.cn/gongbao/content/2006/content_185117.htm, retrieved on 8 December 2017) issued in 2005, the government proclaims that cultural heritage includes tangible and intangible cultural heritage. While the concept of tangible cultural heritage follows the concept of cultural relics as stipulated in the LPCR, the concept of ICH largely adopts the definition in Article 2 of UNESCO's 2003 *Convention for the Safeguarding of the Intangible Cultural Heritage*. The Chinese government ratified the *ICH Convention* in 2004 and quickly issued the *Opinions of the General Office of the State Council on Strengthening the Protection of Intangible Cultural Heritage of China* (full text see http://www.gov.cn/zwgk/2005-08/15/content_21681.htm, retrieved on 8 December 2017) in 2005.

As delineated in above sections, the notion of cultural heritage in China developed from object-oriented cultural relics to an inclusive concept of cultural heritage. Recently, new cultural heritage elements are added into the scope of cultural heritage, such as cultural landscape, cultural routes, and industrial heritage. As the concept of cultural heritage in China has been dramatically extended in spacial and temporal dimensions, new issues emerged in Chinese cultural heritage management system.

The Management System: Characteristics

As described in the previous sections, China has established a relatively complete epistemological system of cultural heritage in its official heritage discourse in the 2000s. However, China's cultural heritage management in practice develops more slowly than the evolution of the heritage discourse. To a large extent, this management system is still primarily based on the tangible-oriented management system which emphasizes cultural relics, a similar situation which is also found in other countries (Smith 2006). Influenced by the deep-rooted administrative system developed in the times of the planned economy, Chinese cultural heritage management system has its own characteristics: public ownership, nonprofit administration, and hierarchical localized management (Liu et al. 2008). In this and the following sections, the management system is analyzed from the aspects of the system (actors), the regime (organizations), and the mechanism (operations).

Public Ownership

The principal status of the socialist public ownership is stipulated in Article 6 of *China's Constitution* (full translation is on http://www.cpd.com.cn/gb/flfg/2003-04/11/content_1821.htm, retrieved on 8 December 2017). Accordingly, the management system of cultural relics in China was established as a nonprofit enterprise of China's public welfare undertakings. The ownership of cultural heritage, according to the LPCR, concerns state's ownership, collective ownership, and private ownership. In general, the majority of Chinese cultural heritage is owned by the state. Article 5 of the LPCR stipulates:

> All cultural relics remaining underground or in the inland waters or territorial seas within the boundaries of the People's Republic of China re owned by the State. (. . .) Such immovable cultural relics such as (. . .) except where otherwise provided for by regulations of the State, are owned by the State. The ownership of State-owned immovable cultural relics shall remain unchanged when ownership or the right to use of the land to which such relics are attached changes (Full official translation is on http://www.sach.gov.cn/art/2007/10/29/art_1034_6944.html, retrieved on 8 December 2017).

It has to be pointed out that emerging non-governmental social actors, such as companies and organizations, began to participate in the ownership reform of Chinese cultural heritage after the 1980s, such as in the fields of heritage tourism and museums. However, the public ownership still dominates the current cultural heritage management system in China.

Nonprofit Administration

The principal status of public ownership in China leads to a nonprofit management system which can be examined from the aspects of the subject of administration, the system of administration, financial resources, income distribution, and public shareability.

Generally speaking, the subject of administration of Chinese cultural heritage concerns the public institutions funded by the government or a heritage sector of the government. Public institution is a unique sector in China as it functions across the sectors of government, company, and nonprofit organization. At every administrative level of China (from national, provincial, municipal to county), the government establishes, funds, and regulates a series of public institutions to provide nonprofit social undertakings, such as heritage, education, health undertakings, and so on (Zhang 2006). This means that cultural heritage is directly managed by a public institution or a heritage sector which are affiliated to the government at a certain level. Because of this administrative structure, the authority and function of the subject of administration ultimately belong to the government at an according level. This administrative system also means that the incomings and outgoings of the management are regulated by the according government. In general, all the expenses of management are financed by the government; meanwhile, the majority of the operating revenues, such as the admission fee or social donations, are usually turned over to the according government. In China, this financial system is called "separation between revenue and expenditure." Here, it is easy to see that the management and operation of cultural heritage is not for profit making but for the public benefit. In later sections, the drawbacks of this administrative system will be examined in terms of hierarchical administration and financial scheme.

Hierarchical Localized Management

In line with China's national administrative system born in the era of the planned economy, the macrostructure of Chinese cultural heritage management system can be described as the one which is "combined with Tiao and Kuai while dominated by Kuai," which means cultural heritage is managed, horizontally, by multiple sectors at the same administrative level and, vertically, by hierarchical public institutions and/or heritage sectors (Lu 2004; Wang and Zhu 2006; Liu et al. 2008).

Chinese word Kuai (块) describes the segmented governmental sectors at a certain level of government which manages different aspects of cultural heritage, according to the attributes of the heritage. The State Administration of Cultural Heritage (SACH hereafter), as a major subject of cultural heritage management at the national level, is responsible for the protection, administration, and supervision of most cultural heritage in China. (The duties of the SACH are available on http://www.sach.gov.cn/col/col1020/index.html, retrieved on 8 December 2017.) In addition to the system of the SACH, nevertheless, cultural heritage can also be managed within the systems of the Ministry of Housing and Urban-Rural Development (e.g., National Scenic Spots), the Ministry of Culture (e.g., ICH), the China National Tourism Administration (e.g., some heritage tourist attractions), the State Archives Administration of China (e.g., some historic archives), and the administrations concerning ethnic affairs, religious affairs, education, and military. Clearly, this Kuai segmented administration inevitably leads to an intersecting management where cultural heritage is actually managed by multiple government sectors.

Chinese word Tiao (条), in the vertical dimension, describes the hierarchical administration from the national level to the county level. As stipulated in Article 8 of the LPCR, local governments are responsible for the management of cultural heritage which is located in its administrative region. Consequently, cultural heritage is hierarchically managed by local governments at different levels, according to the grade of heritage. At a certain governmental level, the public institution or heritage sector functions under the administration of its upper-level counterpart. At the same time, this vertical hierarchical administration can also be described as a principal-agent system. As a principal of Chinese cultural heritage, the Central Government (and its heritage-related sectors) entrusts the ownership and management rights of cultural

heritage to the lower/local governments (and their heritage-related sectors), who, then, entrust the ownership and rights to their heritage-related public institutions at the according level. Consequently, local heritage-related public institutions, such as cultural heritage protection units (for most immovable cultural relics) and museums (for most moveable cultural relics), are the ultimate agents who exert management rights in reality.

In conclusion, the macro management of Chinese cultural heritage is characterized by the combination of Tiao and Kuai, the hierarchical principal-agent system, and an intersecting management which is attributed to the Kuai segmentation. While such a system benefits China's cultural heritage in the times of the planned economy, drawbacks of this system emerged in times of transformation after the Open Policy reform (Fig. 1).

The Management System: Issues

After the Open Policy reform, modernization is regarded by the Chinese government as both a material and spiritual enterprise (Shepherd and Yu 2013). Thus, current cultural heritage management in China is entangled with the political situation, economic development, and cultural policies (Zan 2014). After comprehensive surveys, Chinese scholar pointed out several noticeable issues in relation to the protection and use of cultural heritage in China: insufficient protection, irrational use, and a flawed management system (Lu 2004). These practical problems can be classified as inner institutional causes of the management system and managerial deficiencies of the system in practice (Liu et al. 2008).

Institutional Causes

Liu et al. (2008) argue that, from the most fundamental one to the most visible one, there are three inner causes resulting in the management system: the most fundamental cause is the deviation in the management idea, an important cause is dissymmetry between the revenue authority and expenditure liability, and the most direct cause is the unsound supervisory mechanism.

It can be seen from the previous section that the Chinese government emphasizes the materiality of heritage, as well as the intrinsic and static historical, artistic, and scientific values of tangible heritage. This official heritage discourse leads to a result that cultural heritage is usually regarded as an object for scholars or experts for their academic studies. This can be clearly seen from, for example, official's statements that cultural heritage, either tangible or intangible, is a "witness of historical development of human society" (Li 2002, 1; Xin and Huang 2011, 193). Since the reform of the market economy system in the late 1980s, nevertheless, the economic value of cultural heritage has been gradually privileged by the government, especially the local governments. It is common to find in many cases that the use of heritage for economic functions, such as in heritage tourism, tends to overtake the public benefit. International scholars even argue that economic development is the principal problem of China's tangible cultural heritage (Blumenfield and Silverman 2013). Government's imbalanced understanding of the values and function of cultural heritage therefore lies at the center of the flawed management system.

As illustrated before, cultural heritage management in China follows a hierarchical principal-agent measure. While this method activates local governments to manage cultural heritage on behalf of the central government, it also results in a series of practical issues, in particular the imbalanced protection and use of cultural heritage. On the one hand, the grade of the values of cultural heritage does not correspond with the hierarchy of the government. For instance, a national key protected cultural heritage is likely to be directly managed by a county government sector. On the other hand, restricted to the revenue authority, as well as staff and other administrative resources, lower-level governments and affiliated heritage institutions have to burden disproportionate management of the heritage, many of which are of great values. Consequently, the local government is likely to try rent-seeking in the market, with the results that the economic value is privileged, the public benefits is neglected, and the social function of heritage is restricted.

China: Cultural Heritage Management, Fig. 1 The Tiao and Kuai Systems in Chinese heritage management

Deviation in the management idea and dissymmetry between the revenue authority and expenditure liability contribute to the third institutional cause - weak supervisory mechanism-the most direct reason behind the tension between protection and economic use of heritage. This cause can be examined from two aspects. The first concern the weak restrictive and supervisory mechanisms in Chinese cultural heritage management system (Lu 2004). Among these, the lack of legal restrictive mechanism is important. While economic development is widely emphasized by local governments, the position of heritage-related government sectors and institutions is usually weakened.

This situation becomes severe as there is no stipulation of responsibility-tracking system in current cultural heritage-related laws. Thus, it is common to find in China that cultural heritage protection inevitably gave way to real estate, commercial, and tourism development projects.

The second concerns the public supervision. Considering Laurajane Smith's argument of Authorised Heritage Discourse (Smith 2006), it can be seen that the discourse and managerial practice of cultural heritage in China are largely dominated by an Authorised Heritage Discourse (Wu and Qin 2016). While the Chinese Authorised Heritage Discourse is a top-down operation, the general public rarely take initiatives to participate (Harrell 2013). Although the public benefit is gradually facilitated by the government, general public's cultural rights to cultural heritage are still not fully stipulated in heritage-related laws.

Managerial Deficiencies

Generally speaking, the level of Chinese cultural heritage management needs to be improved. As concluded by Liu et al. (2008), there are at least three reasons behind the managerial deficiencies: lack of administrative resources, unbalanced allocation of administrative resources, and imperfect implementation of the macro national policies.

One of the most significant restrictions on management, as indicated before, is that local heritage institutions lack revenue authority and sufficient administrative resources, such as staff and equipment. Meanwhile, the operation of management largely depends on a single and insufficient financial investment from the according government. The distribution of national administrative resources is not even across the country. As illustrated before, local governments are the agents who are responsible for the cost of management. Nationally speaking, the distribution of cultural heritage resources across different provinces and regions is not even, as well as the fiscal revenues. Therefore, provinces or regions with abundant heritage recourses may face severer funding problems than other places. According to a national survey of the management of national key protected cultural heritage units, for instance, scholars (Liu et al. 2008) found that Xinjiang, Gansu, Ningxia, Hubei, Jiangsu, and Fujian are the provinces which own generally high level of cultural heritage values but lack management effectiveness and governmental investments. Accompanied with this issue is the drawback of current decision-making mechanism in local government. Having limited understanding of the macro picture of regional cultural heritage resources and lacking scientific planning and decision-making methods, local leaders usually obey their personal ideas or follow the opinions of certain experts or stakeholders.

The management of cultural heritage in China has always been influenced by the macro national policies. In the new century, the central government issued several beneficial policies for economic and social development. Given the fact that the development and administrative resources are not even across the country, it is common to notice the gaps between policies and implementations, as well as between cities and countryside. For example, the central government initiated the Construction of New Socialist Countryside in 2005 to improve the economic, political, cultural, and social constructions, as well as cultural heritage protection, in Chinese countryside. While this national policy activates local governments to "modernize" and "beautify" the countryside, it is unfortunate that some cultural heritage, both tangible and intangible, are harmed in the campaign when a gap exists between the comprehension and the implementation of the national policy. China has experienced an unprecedented urbanization when many heritages in cities were destructed. However, there is still a danger that the authorities in countryside regard the Construction of New Socialist Countryside as another "new village construction" or "urbanization" (Yuan 2006). In some cases, as a result, standardized concrete buildings replaced the unique vernacular buildings, and modern lifestyle tempted the villagers to give up their traditional lifestyle. In this way, divergences are likely to emerge between the original proposition of the national macro policy and the implementation in the local area.

Major Practical Problems in the Management

Scholars have observed a series of practical problems of cultural heritage management (e.g., Lu 2004; Liu et al. 2008, 2009; Shepherd and Yu 2013; Blumenfield and Silverman 2013). A central goal of Chinese cultural heritage management is to well balance the relationship between protection and use of cultural heritage. In general, institutional causes and managerial deficiencies of the management system are accountable to most of the current practical problems. The majority of these problems can be classified into two aspects: weak public benefit function and irrational economic function.

In the first place, cultural heritage should be regarded as a public resource that every community member can benefit from. However, public benefit of heritage is not well delivered to the public. The deep-rooted institutional cause that Chinese heritage management idea emphasizes the materiality of heritage results in a fact that the public has not been centered in the whole heritage undertaking. Therefore, there is still a noticeable gap between the cultural products and services provided by the heritage institutions and general public's burgeoning cultural needs. This issue is reflected in museums and immoveable cultural relics. In the field of museum, generally, the quality of exhibition is relatively low, the content and interpretation is tedious, and the art derivative products are not well-developed. For example, during the making of a "City of Museums" in Shanghai in the 2000s, around 80% of the newly launched museums are industry museums. Nevertheless, except those established in the industries of tobacco and bank, the majority of the industry museums are unable to normally operate in the long term. Nationally, according to Lu's report (Lu 2004), less than 1% of the moveable cultural relics collected in Chinese museums were displayed to the public. This figure, in the Palace Museum for example, was still 0.5% in 2015 (Liu 2015). As far as immoveable cultural heritage is concerned, except the famous scenic spots, the majority of them are not fully opened to the public (Lu 2004). This issue can be seen in the fact that, among 4296 national key protected cultural heritage units, over 50% of them were not opened to the public in 2015 (Yang 2016). Unless heritage sites can reward with noticeable economic or social benefit, as a vanity project, the local government usually is reluctant to invest in the protection and management.

Conversely to the under-function of public benefit, irrational economic development of cultural heritage becomes a central concern in the management. In general, this problem relates centrally to the tension between protection and use of cultural heritage. Furthermore, this tension can be analyzed in two aspects: the first is irrational economic development of heritage tourism or heritage commodification, and the second concerns the conflicts between heritage administrators and other non-heritage-related stakeholders.

Irrational economic development is often found in the tourism commodification of immoveable cultural relics. Because of its high cultural values, most immoveable heritage is regarded by local government as tourism attractions. Unfortunately, the existence of the institutional causes means that local government tends to privilege the short-term economic reward, with the result that cultural heritage is commodified in the tourism market as a local asset. In some cases, the ownership and operational right are detached so that the former is retained in the heritage institution and the latter is operated by a company. Thus, the heritage managed in this mixed method is usually over-commodified and overused, and the protection is inevitably overlooked. For example, the Shaanxi Tourism Group was established in 1998, and it took the operational rights from the government of five national key protected cultural heritage sites in Shaanxi, including the Mausoleum of the First Qin Emperor and the terra-cotta Warriors and Horses. However, soon the managerial problems appeared, and meanwhile, "destructive protection" of the site and harm to material authenticity are noticed (CYN 2002).

The conflicts between heritage-related sectors or heritage institutions and other non-heritage-related stakeholders become increasingly serious along with China's fast economic modernization. This problem is usually found in the conflicts between heritage protection and infrastructure construction projects and/or urbanization. One of

these serious cases can be found in the site of Great Wall in Hohhot, Inner Mongolia. A section of 100 meters of the Great Wall dated back in the Qin and Han period (B.C. 221–A.D. 220) was severely damaged during a drilling project by a local mining company in 2009 (Zhang 2009). This lawless destruction was so rude that the local heritage sector had tried many times until they can finally stop this ruthless behavior. In addition, urbanization and fast city infrastructure construction, which is common in nowadays China, is another major threat to heritage management. For example, in the name of "reconstruction of the old town," the majority of the old buildings and the old block of the Old Town of Dinghai in Zhoushan City, the only island historic town of China, was ruthlessly destroyed from 1997 to 2000. Local government's decision to dismantle the old town was so strong that the heritage institutions' dissuasion, the local citizens' lawsuit, and the media's supervision didn't stop this heritage catastrophe (Guangming 2000). In China, this government behavior is ironically described as "destroying authentic cultural relics and fabricating inauthentic antiques."

The Management System: Reforms

As revealed in the previous sections, China's political and economic system and administrative resources, as well as the government's perception on the values and functions of cultural heritage, shaped the current management system of cultural heritage. Under the background of national macro political and economic reform since the Open Policy in 1978, in particular the market economy system reform, many practical marketization reform approaches have been proposed in the field of public welfare. In order to adjust the tension between the economic development and reform of the society and the stereotyped heritage management system, local government, as well as the heritage administrative sectors, began to experiment on the management reform in order to address two major issues: insufficient revenue and inefficient management. The management reform was firstly experimented in the field of immovable heritage sites. Depending on the management objectives, there are generally two kinds of management system reform: the first is marketization reform, and the second is non-marketization reform.

Marketization Reform

Liu et al. (2008) concluded that there have been generally two forms of market-oriented reforms of cultural heritage management in China in the past two decades: the first is a profit-oriented marketization reform (including listed company-oriented reconstruction, tourism resources integration, and joint-stock reconstruction), and the second is a nonprofit marketization reform.

All three types of reform in the form of profit-oriented marketization inevitably concern the reconstruction of ownership and operational rights. The first type of profit-oriented marketization, listed company-oriented reconstruction, began in World Cultural and Natural Heritage Mount Huangshan in An'hui Province. The reform in Huangshan was triggered by Deng Xiaoping's historical visit in 1979 so that it can also be regarded as the initiative of Chinese tourism (Wu et al. 2016). Huangshan was listed as a World Heritage in 1990 and a reconstruction plan for a listed company plan was initiated in 1996 when the first Chinese tourism concept stock, Huangshan Tourism, was listed in the stock market. The institutional reform resulted in one institution with two functions: the one is Huangshan Tourism Group, and the other is Huangshan Management Committee. (In Chinese this situation is called "Yige Jigou Liangkuai Paizi" (一个机构, 两块牌子).) With the obtained operational and exploitation rights, the former runs all business in Huangshan, while the latter only has the ownership and protection rights. The positive result of this reform is that the reconstructed institution can better deploy the administrative recourses and operate tourism business. However, the most significant negative effect is the lack of administrative supervision for heritage protection.

The second type of profit-oriented marketization reform, tourism resources integration, can be best exemplified in the case of Shaanxi Tourism Group. Under the arrangement of the provincial

government, the operational rights of five national key protected cultural heritage sites, including the Mausoleum of the First Qin Emperor and the terra-cotta Warriors and Horses, were integrated and transformed to the newly established Shaanxi Tourism Group in 1998. However, many severe managerial problems emerged when these high-value heritage sites are managed and operated by the company alone. For instance, the appearance and historic environment of the Mausoleum was altered for tourism; in addition, the admission revenues of the terra-cotta Warriors and Horses were collected as business profits (HSD 2002). This reform was later suspended and the managerial rights of all cultural heritage sites were finally returned to the provincial cultural heritage administration in 2007.

The third type of profit-oriented marketization reform refers to a reconstruction in which, profit-making organizations, such as state-owned capital and private capital, participate in the management in a joint-stock method. This reform is exemplified in the case of Sankong cultural heritage (including the Confucian Mansion, the Confucian Temple, and the Cemetery of Confucius) in Qufu, Shandong Province. In 2000, Confucius International Tourism Company, a joint-stock company, was established to manage and operate Sankong, while the previous administrator, Qufu Cultural Relics Management Committee, was only able to supervise the cultural heritage. However, the supervision was so weak that a serious damage was done to cultural heritage in Sankong in 2000: the company used running water to wash the historic wooden structures, which damaged most of the surfaces of the buildings, as well as the collected moveable cultural relics and steles (Baidu Baike 2017). One year later after the incident, under the request of the higher-level government and the condemn of the media, the joint-stock company handed over the managerial rights to Qufu Cultural Relics Management Committee.

Nonprofit marketization reform indicates an approach that companies participate in the management with their capital or resources. Different from the previous profit-oriented marketization reforms, the company cooperates with governmental heritage sectors without asking for economic reward. This reform is relatively new in China, and one of the experiments can be found in the management of the Nanyue Kingdom Sluice Museum in Guangzhou, Guangdong Province. In 2000, the sluice site was found accidently in a construction project of a commercial complex by the Guangming Company. Then this site was excavated, protected, and turned into a free-of-admission museum after a negotiation between Guangzhou cultural heritage sector, construction sector, and the company. The museum is finally situated on the ground floor of the commercial complex, and the company has to cover the construction and everyday maintenance of the museum. This approach is generally praised as a win-win method with which the financial shortage of government is compensated, cultural heritage protection and commercial development are well balanced, and the public benefit of heritage is secured. Nevertheless, problems in its management still emerged in recent years: the company is suffering from the protection and maintenance expenses, and a sound communication mechanism between the company and the heritage sector is needed (Huang 2017).

Non-marketization Reform

Compared with the abovementioned marketization reform where profit-oriented companies are involved, nonprofit or nongovernmental organizations are not active in the management in China. In contrast to Western countries, the power of nonprofit or nongovernmental organizations in China is weak and underdeveloped. There are at least three major reasons (Zhang 2011). The first is the basic institutional cause that the ownership of the majority of cultural heritage belongs to the state so that it is difficult for nongovernmental organizations to intervene in this bureaucratic administrative system. The second institutional cause concerns the underdevelopment of relevant laws or regulations for, and the difficult application process of, a nongovernmental organization. The third reason is that a supporting tax exemption system is yet to be established so that there are only a few nongovernmental organizations in China (35 organizations as of 2008) who are qualified for preferential tax policies.

Although nongovernmental organizations' engagement in heritage management experiences difficulties, they are encouraged by the government to participate in the field of cultural industry, in particular in the field of museum. This is mainly because, compared with immoveable heritage sites which are predominately owned by the government, moveable cultural relics can be owned by individuals, legal persons, or organizations. In the 2005 *Several Decisions of the State Council on the Entry of Non-public Capital into the Cultural Industry* (full text is on http://www.gov.cn/zhengce/content/2008-03/28/content_5680.htm, retrieved on 8 December 2017), the structure of Chinese cultural industry is descried as the one where public ownership remains the mainstay and multiple forms of ownership develop side by side. Specially, nonpublic capital is encouraged in the field of museums and galleries. This policy is further detailed in the *Ordinances on Museum* (full text is on http://www.gov.cn/zhengce/2015-03/02/content_2823823.htm, retrieved on 8 December 2017) in 2015. In Article 4, it is stipulated that companies, social organizations, citizens, and other social actors are encouraged to establish museums. Meanwhile, these non-state-owned museums are equally considered as state-owned museums in management, including fiscal and tax supporting policies. According to a statistics (Xinhua 2015), there were 982 non-state-owned museums in China as of 2014, accounting 21.8% of Chinese museums.

In general there are three operating mechanisms of Chinese non-state-owned museums (Zheng 2010). The first form of museums is operated by a foundation and/or a council. The best case is Guanfu Museum (official website of Guanfu Museum is http://www.guanfumuseum.org.cn/, retrieved on 8 December 2017), the first private museum in China which was established by the famous Chinese collector Ma Weidu in 1996. In its early years, Guanfu Museum experienced financial difficulties. Later, Ma introduced the council system and established a foundation which is benefited from successful Western models such as the Guggenheim Foundation. Now Mr. Ma is quite confident about the future of his museum, and he has launched branch museums in Shanghai and Xiamen, following the Guggenheim model. The second form of museum is operated and sustained by a company. This form can be exemplified by China Red Sandalwood Museum (official website of China Red Sandalwood Museum is http://www.redsandalwood.com/en/, retrieved on 8 December 2017) which was established by Chen Lihua, Chairwoman of the board of Fuwah International Group in 1999. The third form combines the benefits of the first and the second forms. Today Art Museum (official website of Today Art Museum is http://www.todayartmuseum.com/enexhibitons.aspx?type=currentexh, retrieved on 8 December 2017) is an art museum which was initially funded by a company but later underwent a joint-stock reform of its ownership. The curator of Today Art Museum, Zhang Baoquan, who is also the Chairman of the board of Antaeus Group, regards it is not sustainable to fund the museum with only one company. Therefore, he invited several other companies to subscribe the shares of the ownership. In addition, a council is established to act as the highest managerial body of the museum.

As these non-marketization reforms firstly appeared in most of non-state-owned museums in China in the late 1990s, the SACH introduced the council system to reform the management of public museums in an official document in 2010. Recently in September 2017, seven central ministries issued *The Implementation Plan of a Thorough Advancement of the Corporate Legal Person Governance Structure Reform in Public Cultural Institutions* (full text is available on http://www.sdwht.gov.cn/html/2017/whb_0912/42778.html, retrieved on 8 December 2017) which requires public museums to advance the establishment of the council system. This reform is within a broad context of the reform of state-owned enterprises and public institutions in China. Specifically, the goals of this reform are to establish a corporate legal person governance structure of council system so as to transform the government functions, to activate the agencies of museums, and to promote the participation of social actors in the cultural field.

The first group of experiments were carried out in provincial museums in Yunnan (in 2014), Guangdong (in 2014), Hunan (in 2015), and Henan (in 2015) Provinces. In an interview of Director Dai Zongpin from Yunnan Provincial Museum (Sina 2016), for example, the council is consisted of 15 members equally selected on the basis of a negotiation from three sources: the museum, the government, and the local society. In regard to the structure of the management system, for instance, Director Duan Xiaoming from Hunan Provincial Museum introduced that they constructed a three-level mode: the supervision and management rights held by the Provincial Department of Culture, the decision-making rights held by the museum council, and the management and implementation rights held by the management team of the museum (Sina 2016). During this reform there exists, however, a tension in the relationship between the governmental heritage sectors and the museum council, as pointed out by these two directors. As a result, the museum mediates this tension by adopting relevant heritage officials as members or even the president of the council. The same as other heritage institutions in China, the conventional management system of Chinese museum blends the characteristics of both corporation and social organization. Therefore, the aim of cultural reform in the museum field is to separate governments and institutions, as well as to separate supervision and operation. However, as noted in the experiment, the tension between the government and the council still exists as long as the current administrative and personnel management system remain.

It can be seen from above illustration that Chinese cultural heritage management system needs to be reformed from both the inside and the outside. The inside reform concerns the institutional causes and managerial deficiencies of the administration, while the outside reform means the participation of social actors in the heritage management. Reforms were first seen in the management of immovable heritage and recently in the field of museums. As observed by Chinese scholars recently (Su et al. 2016), however, reforms of the management system and the managerial ability of the heritage sectors and public institutions still have a long way to go.

The Management of Intangible Cultural Heritage

As introduced in section "Management of Cultural Heritage After 1985", the concept of cultural heritage in China is a newly conceptualized one which incorporated the concept of ICH into its long-existing concept of cultural relic, the synonym of tangible cultural heritage. Chinese cultural heritage management system, as discussed in the previous sections, is therefore predominately built on the management of immovable and movable heritage. As the concept of ICH has been introduced into Chinese heritage discourse in 2004, however, a comprehensive and unified cultural heritage management system which comprises that of ICH has not been established. In particular, ICH is managed by another system under the jurisdiction of the Ministry of Culture.

China is an active player in UNESCO's ICH undertaking. As soon as China ratified the ICH Convention in 2004, the State Council issued an official document to advance the protection of ICH in China in 2005, and later in 2011, the *Law on Intangible Cultural Heritage of the People's Republic of China* was enacted. Within 7 years, the Chinese government strongly advanced the protection of ICH and has established a relatively complete management system of ICH in China. In general, this government-led management system comprises of three parts: the leading agency is the Joint Meeting of the Inter-ministerial Working Conference System; the managerial agency is the Ministry of Culture and its subordinate cultural administrative agencies in local governments; and the executing agency is the ICH Protection Center (Han 2011).

Realizing the comprehensiveness of the categories of ICH, as well as the segmentation of the administrative rights across different sectors (the segmentation of Kuai), the State Council established the inter-ministerial joint meeting system as the top decision-making organ. This

system is led by the Ministry of Culture and is attended by delegates from other eight national ministries/agencies such as the SACH, the Ministry of Education, the State Ethnic Affaires Commission, and so on. Directed by this joint system, practical administration is coordinated by the Department of ICH at the Ministry of Culture which was established in 2009. This is the highest administrative agency in China to deal with the ICH policies and national issues. Following this organizational adjustment, the majority of Chinese provinces established their own Divisions or Sections of ICH within the provincial Department of Culture. Consequently, similar Sections or Offices of ICH are established by local governments at municipal and county levels (the hierarchy of Tiao). Thus, a hierarchical administrative system within the Ministry of Culture is structured at national, provincial, municipal, and county levels accordingly, in the same way as that of tangible cultural heritage within the SACH system.

While cultural heritage protection units and museums are the two ultimate agents who exert management rights in the tangible heritage field, the ICH Protection Centre is the executing agency in the ICH field. At the national level, in accordance with the adjustment of the Ministry of Culture, the Chinese National Center for Safeguarding Ethnic Culture and Folklore, a national public institution launched in the Chinese National Academy of Arts in 2003, was renamed as the China ICH Protection Centre in 2006. Following this "top-down" manner, the majority of Chinese provinces have established their ICH Protections Centers at provincial, municipal, and county levels. At each of the governmental level, the ICH Protection undertakes the practical ICH protection works, such as investigation, documentation, and the operation of transmission, under the administration of the Division/Office of ICH at the according level.

Compared with the tangible heritage management system, a characteristic of the ICH management system is that experts and/or scholars in relevant fields are greatly encouraged to particulate in the implementation of national ICH policies in practice. The role of experts in Chinese ICH management is pointed out in the State Council's opinions in 2005 and the Ministry of Culture's notification in 2006. In the latter, specifically, the Ministry of Culture requires a national Committee of Experts established as a national consulting institute under the direction of the office of the Joint Meeting of the Interministerial Working Conference System. This Committee of Experts, however, is not only comprised of scholars/experts but also officials working in the ICH related government sectors. They are convened regularly by the government to form the committee to recommend, authenticate, and review the listing of ICH candidate elements and representative inheritors at the national level. Following this structure, the subordinate Committee of Experts has been established at provincial, municipal, and county levels. In particular, the local Committee of Experts is convened and directed by the ICH Protection Centre at the according levels. Thus, the experts and scholars in relevant fields are incorporated into the governmental management system of ICH at the according levels. This close relationship between the government and the experts/scholars can also be termed as the symbiotic government-scholar network (Maags and Holbig 2016).

This section delineated the general characteristics of the ICH management system in China. By comparison, this system is similar to the tangible heritage one which is characterized by the horizontal Kuai segmentation and the vertical Tiao principal-agent system. Looking from a broad picture of Chinese cultural heritage management system, the existence of this relatively independent ICH system reflects another Kuai segmentation between the tangible and the intangible heritage sectors. This divergence remains an issue to be considered in the future reform in China.

Conclusion

Chinese cultural heritage management is a complex one which is characterized by political, cultural, and economic features. As illustrated in this entry, the concept of cultural heritage in China initially is derived from the tangible-centered concept of cultural relic in the ancient times. Afterward, it incorporated international heritage concepts after the 1980s and developed into the current concept of cultural heritage. In general, the

government dominates the discourse of cultural heritage, forming an Authorised Heritage Discourse which is similar in many other countries in the world (Smith 2006). Consequently, this official discourse directs the heritage management in practice. As demonstrated in this entry, the perception of the government on the nature and values of heritage therefore leads to the formation of the management idea. In addition, as part of a macro administrative system born in the times of the planned economy, the management system of cultural heritage is characterized with several institutional features and managerial deficiencies. The most noticeable feature is the hierarchical localized heritage management system characterized by the Kuai segmentation and the Tiao principal-agent system. These characteristics, however, are challenged after the Open Policy reform in the late 1970s. On the one hand, China began to reform its economic and political system for modernization; on the other hand, China tried to internationalize its heritage management on the world stage. Although reforms are seen in the fields of immovable heritage sites and museums, Chinese cultural heritage management system still needs further reform and improvement. This situation is complicated by the emerging conflicts between the economic development, urbanization, and industrialization, cultural protection, and general public's cultural needs. These are the issues that Chinese government will have to address with the participation of the emerging social actors in the long term.

China: Cultural Heritage Management Education

Junmin Liu
School of Cultural Heritage, Northwest University, Taibaibeilu, Xi'an, China

Introduction

After the founding of New China, the Communist Party of China begins to devote more attention to the preservation of cultural heritage and carries out the preservation measures effectively.

Key Issues/Current Debates/Future Directions/Examples

Legislation and Preservation

The legislation of the cultural relics preservation is a long and gradual process. In 1961, the State Council enacted "the Temporary Rules of the Preservation and Administration of Cultural Relics" which set up the class-rate system of cultural relics. In November 1982, as the Law of the Preservation of the Cultural Relics was promulgated, the preservation of the cultural relics became institutionalized. At the end of 2005, "the Notice on Enhancing the Cultural Heritage Preservation" was announced by the State Council, which used the word "cultured heritage" as the key word for the first time. From the publication of the First List of the National Level Cultural Relics Sites to the Sixth List, the concept "cultural relics" has been deepened and widened; the preservation focus has shifted from the single site to the setting of the site and to its historical space even the historical district and the town. The connotation and denotation of cultural heritage is developing constantly.

Furtherance of the Concept Preservation

The concept preservation of cultural relics is updating continuously. In the early period, the display and utilization of cultural heritage has been excluded from the range of the "preservation" which is a kind of negative and isolated preservation. In 1992, the National Cultural Relic Work Meeting came up with the working principle "Preserve firstly, save primarily." In 2002, in order to solve the problem between the economic development and cultural relic preservation in the market economy, the Law of Protection of Cultural Relics puts forward the basic principle "Preserve primarily, save firstly, utilize reasonably, and manage intensively." This principle requires rational, proper, and scientific

utilization in the preservation of cultural relics; helps to resolve the argument about the relationship between preservation and utilization; and makes our preservation policy more complete, definite, and practical.

School Education

The cultural heritage education in China can be divided into two parts: school education and public education. Universities play an important and creative role in the heritage conservation, research, and training. Since the establishment of the archaeology major in Beijing University in 1952, archaeology has attracted more and more attention and great achievements have been made. Now archaeology and museology have become two major subjects in many universities, such as Northwest University, Zhengzhou University, Jilin University, Nanjing University, Shandong University, and Sichuan University. Beijing University has been the pioneer to start the course "World Heritage" and built a professional research organization – the World Heritage Research Center which has been regarded as the symbol of the new stage of Chinese World Heritage Research. After that, a number of research institutions have founded Cultural Heritage Research Organizations in succession. The Conservation and Plan Center set up in 2004 by Northwest University and the Cultural Relics Bureau of Shaanxi Province will perform a leading role in the preservation of cultural relics in Northwest China. Just two years later, the two organizations built a Cultural Heritage School which features two majors: Archaeology (including the Management of Cultural Heritage Direction) and Restoration and Protection of Cultural Relics. To our joy, in 2007, the Ministry of Education established the Cultural Heritage Research and Conservation Key Lab which focuses on relevant research on cultural heritage, conservation plan, and preservation technology. What is more, it promotes professional training and development of the cultural heritage conservation in Shaanxi Province. Thus, three major subjects come into being in the field of Chinese cultural heritage. They are, respectively, the Archaeology, the Museology, and the Cultural Heritage Research.

Public Education

Cultural heritage concerns not only the professionals but also every average people in the society. Therefore, the public education of cultural heritage by no means cannot be ignored.

Since 2006, the Chinese government has set up Chinese Cultural Heritage Day on which the government will organize various and abundant relevant activities to arouse public's consciousness of cultural relics preservation, encourage public participation, and help the public to deepen their understanding of the preservation of cultural relics.

Museums are the major places and propagating platforms for cultural heritage conservation. During the 11th Five-Year Plan Period, there are 1743 museums and bases for patriotism education, and memorial museums open to public for free. With these efforts, the number of spectators is increasing. As a result, more and more people have the chances to visit these museums and extend their knowledge in archaeology and its preservation. Consequently, a growing number of the public begin to appreciate and experience Chinese brilliant cultural heritage in this way.

In our daily life, through media like books, newspapers, and films, we can easily narrow the distance between cultural heritage conservation and the public. With the purpose of improving the public's conversation consciousness and attracting public attention and participating, we utilize media like the Internet, television, newspaper, exhibition, and lecture to promulgate sustainable developments of cultural heritage, to publicize the relevant knowledge of laws and conventions on cultural heritage conservation, and to arouse public's awareness of preservation. Since the year 2000, a series of popular reading, academic books, and symposiums have been published gradually. As to the Internet, the nonprofit Internet sites about historic cultural heritage and world heritage have been set one after another. These sites offer the public the general knowledge in heritage exhibition and inspection and help to exchange ideas between the professionals and the amateurs. And the national academic forum has been held every year. What is more, the China Cultural Relics Research Institution has grown rapidly and been renamed the

Chinese Academy of Cultural Heritage, a national level institution of cultural heritage. Accordingly, cultural heritage education enters a brand-new stage.

MAC-DUFF Tourism | Heritage | Planning, Ottawa, Canada

Introduction

The earliest written records of Chinese civilization date back to the Shang dynasty in 1600–1046 BC. Prior to that time, there is evidence to indicate that human societies emanated from the Yangtze River's Yangtze civilization millennia ago in the Neolithic era (Boltz 1986). This construct of physical and written evidence is often viewed as a proud lineage of China being one of the world's "cradles of civilization." Since those origins, the rise and fall of dynasties and ongoing reshaping of the concept and borders of China have provided a substantial cultural and natural heritage foundation that has been demarcated and recorded, now serve a range of purposes as part of the national patrimony. One of the primary mechanisms that China has applied to promote and highlight safeguards for its extensive cultural and natural historical resources is through the nomination of many of these significant locations and venues as World Heritage Sites. Since China's ratification of the World Heritage Convention on December 12, 1985, it has embraced the nomination process to now hold the second highest number of designations in the world, after Italy (UNESCO 2017a).

Historical Background

These objectives' purposes have become more evident after the establishment of the People's Republic of China in 1949. This process was accelerated in the post-Cultural Revolution era with the introduction of the Convention Concerning the Protection of the World Cultural and Natural Heritage in 1972, the increase of citizens' personal incomes and discretionary income spending capabilities, and the use of cultural heritage as a tool to promote soft power within China and internationally.

Following the establishment of the People's Republic, the Chinese government overhauled its administration of archaeology and museums. The principal administrative body overseeing archaeology and antiquities was the Ministry of Culture's State Bureau of Cultural Relics. Its responsibilities included a network of 31 provincial-level offices, a publishing house, and academic and professional journals and newsletters. The Institute of Archaeology was established in 1950 within the Chinese Academy of Sciences to oversee archaeological excavation and research (later transferred in 1977 to the newly established Chinese Academy of Social Sciences). Research centers and administrative units were established at the provincial and local levels. Formal training programs in archaeology, conservation, and museum studies were established at Peking University and the Institute of Archaeology in 1952, eventually seeing other

similar departments established at major academic institutions across the country. The Chinese government also established a network of national, provincial, and local museums for archaeology, art, and history, numbering over 2200 as of 2013 (Murochick 2013).

The State Bureau of Cultural Relics (SBCR) is an administrative organ under the Ministry of Culture in charge of relics and museum work in China. The China Cultural Relics Research Institute (CCRRI), founded in 1949, is a research institution under the State Bureau of Cultural Relics, with the task of protecting and conducting research on key national relics, such as ancient buildings, grottoes, temples, unearthed relics, and museum-stored relics. The State Administration of Cultural Heritage (SACH) was established in 2003 and is responsible for the development and management of museums as well as the protection of cultural relics of national importance to protect, regulate, and supervise world cultural heritage and organize applications and examination related to world cultural heritage status (State Council 2014).

In 1982, the National People's Congress promulgated the *Law of the People's Republic of China on the Protection of Cultural Relics* as well as interrelated laws and regulations while delineating the roles and responsibilities of individual levels of government. That same year, SBCR initiated an assessment of the country's cultural heritage resources. By the 1990s, rapid ongoing development had warranted the formalization of a coherent set of national heritage conservation practice and management guidelines.

In 2002, ICOMOS China, with later final approval from SACH, drew up the *Principles for the Conservation of Heritage Sites in China*. These principles drew upon the International Charter for the Conservation and Restoration of Monuments and Sites (the Venice Charter – 1964). According to Article 9, there were six key steps for conservation to be undertaken in the following order: (1) identification and investigation; (2) assessment; (3) formal proclamation as an officially protected site and determination of its classification; (4) preparation of a conservation master plan; (5) implementation of the conservation master plan; and (6) periodic review of the master plan (ICOMOS China 2004). The accompanying *Commentary on the Principles for the Conservation of Heritage Sites in China* has section 15 give specific reference "On Conserving Archaeological Sites, Ruins, and Ancient Tombs." The two key recommended conservation measures are to both ensure treatment of a site's setting by removing elements that could seriously threaten its safety and protection and strengthening of the remains (ICOMOS China 2004).

Further direction was provided through the Central Conference on Urbanization in 2004. Archaeologists were provided guidance principles of giving priority to protection, rescue first, reasonable use, and strengthening the management. In essence, archaeologists were tasked with the responsibility of ensuring the special nature, integrity, the authenticity of ancient cities were preserved and applying a people-oriented approach to relic protection (Ministry of Culture 2015).

To be included on the World Heritage List, sites must be of outstanding universal value and meet at least one out of ten selection criteria. The protection, management, authenticity, and integrity of properties are also important considerations for site management. The World Heritage nomination approach was augmented by the *Global Strategy* introduced in 1994. This Strategy was intended to establish a new vision that expands the narrow definitions of built and cultural heritage and strove to recognize and protect sites that are outstanding demonstrations of human coexistence with the land, as well as human interactions, cultural coexistence, spirituality, and creative expression (UNESCO 2016).

Six locations were nominated as World Heritage Sites in 1987, the first year of China's site submissions to the World Heritage List. These include the five cultural sites of the Great Wall, the Imperial Palace of the Ming and Qing Dynasties, the Forbidden City, "Peking Man" site at Zhoukoudian, the Mogao Grottoes at Dunhuang, Qin Shi Huang Mausoleum, and the Qin Terracotta Warriors and Horses, along with the mixed cultural and natural site, Mount Taishan. This original number has increased almost

ninefold over 30 years. As of September 2017, China has 52 World Heritage Sites (36 cultural, 12 natural, and 4 mixed). There are also 60 properties on their national Tentative World Heritage List, which is viewed as a useful and important planning tool by UNESCO, providing an indication of future nominations (UNESCO 2017a, b).

Key Issues

The sustainability and resiliency of Chinese cultural heritage sites and their archaeological resources are affected primarily by four factors: large-scale development pressures, tourism, natural disasters, and looting.

Development Pressures

Between 1995 and 2015, the urban population in China increased from 352 million to 771 million, mostly in the densely populated eastern seaboard (National Bureau of Statistics 2017). As China's population and economy expand, development pressures are arising in and around cultural sites. Large-scale developments have displaced or removed cultural landscapes and built heritage resources. By 2009, SACH had surveyed and registered 776,200 historical sites including ancient tombs, temples, and historical structures. This recorded total was up by 30%, from the previous 550,300 sites registered in 2007 (Brannigan 2009). It is notable, however, that 23,600 registered cultural sites disappeared from list during that same time, due to major infrastructure projects involving highway, railroad, bridge, and dam construction (Xie 2009).

One of the China's largest infrastructure projects was the construction of the Three Gorges Dam. Beginning in 1994, the dam is a massive structure, 1.2 miles wide and 607 ft high, creating a 370-mile-long reservoir, completed in 2009. The area is also home to cultures that date back to 5000 BC, including the Daxi (ca. 5000–3200 BC), which was the earliest Neolithic culture in the Three Gorges area, the Chujialing (ca. 3200–2300 BC), the Shijiahe (ca. 2300–1800 BC), and Ba (ca. 2000–220 BC) cultures (Childs-Johnson 1996). It was estimated that the area flooded by the dam contained at least 1282 cultural heritage places, which, like the remnants of the cultures that resided there, are unlikely to be recovered (Shen 2000). Other prominent sites were more fortunate. The Zhangfei Temple constructed in the Song dynasty (960–1279 AD) was rebuilt in the same location in 1870 after serious flooding in the region. Its cultural and historical significance was acknowledged with the temple's relocation 2 miles away in 2000, at a cost of US$12 million, during the construction of the dam (Xie 2009).

The Chinese government has reinforced key areas of the Great Wall. Juyongguan, Badaling, and Mutianyu are the closest in proximity to Beijing and have been restored and hardened for tourism purposes. This classical, restored image of the Great Wall is not, however, reflective of the conditions along its length. The Wall has been razed in Inner Mongolia and Hebei provinces to accommodate new road construction. Illegal mining of coal, copper, iron, molybdenum, and nickel has seen portions of the Wall disappear due to explosion impacts on fragile areas and mining equipment removing or displacing wall sections and the underlying archaeological layers (Moore 2011).

Through UNESCO's International Centre on Space Technologies for Natural and Cultural Heritage (UNESCO-HIST) office in Beijing, mapping has been initiated to establish a baseline and monitor physical changes within and along the edges of 40 of China's 52 World Heritage Sites. These selected venues are delineated as groups of buildings, monuments (including rock carving and grotto-based), historical relics, cultural landscape heritage, mixed heritage, and natural heritage (Guo 2013).

Tourism

Over a 20-year period, domestic tourist person-times (each time of traveling is counted as one person-time) surged on an annual basis more than fivefold from 640 million people in 1996 to 4 billion in 2015 (National Bureau of Statistics 2017). There are three busy domestic travel periods during the year: Chinese New Year Period in January/February; Labor Day week, May 1–7; and National Day (Golden) week, October 1–7. Each of these places significant pressure on individual sites, with an estimated 700 million traveling during Golden Week in 2017. Beijing, with its

Tiananmen Square, the Forbidden City, and the Great Wall, tops the list of destinations, according to China's National Tourism Administration (Du Juan 2017).

Many cities in China have the ambition of having a heritage site nominated as a World Heritage Site. The driving factors are increased national and international prestige and crosscutting economic benefits of tourism and associated industries development, alongside the strong competition between Chinese provinces and cities. Since 2004, China has made the first large-scale renovations on six world cultural heritage sites in Beijing – the Ming Tombs, the Great Wall, the Forbidden City, the Temple of Heaven, the Summer Palace, and the "Peking Man" site at Zhoukoudian. All of which were completed prior to 2008, in advance of the higher media profile and international visitor increase during the Summer Olympics.

Cultural sites that were previously very remote and did not receive many tourists are now seeing enormous numbers of domestic arrivals as Chinese citizens now have the means and opportunity to travel. Poor, rural areas bypassed by China's recent economic boom are those most enthusiastic to have sites granted World Heritage status. Local officials often secure significant loans to build infrastructure to support bid preparation, and local residents, at least initially, welcome the opportunity to generate higher incomes, finding work outside farming, and as an alternative to migration.

The Mogao Grottoes is located in a remote northwest corner of Gansu Province. The site comprises nearly 500 Buddhist grottoes cut into a cliff face, containing paintings, painted statues, historical documents, and artifacts, dating from the fourth to the fourteenth centuries. In 1979, prior to nomination, when the grottoes were opened for tourism, there were over 26,000 visitors. Thirty-five years later, in 2013, there were over 800,000 mostly domestic visitors (Getty 2013). Over time, moisture from visitors' breath and sweat was harming the centuries-old cave paintings and Buddhist sculptures, and local traditional communities were being affected by increasing large-scale visitor numbers (Hunt 2012). There are subsequent plans to restrict site visitation to 6000 people per day, down from the current 11,000 daily rate.

Natural Disasters

National disasters, particularly earthquakes and floods, have demolished or diminished World Heritage Sites' cultural heritage integrity in China. Sichuan Province has experienced two major earthquakes in 2008 and 2017 causing destruction and loss of lives. This has also impacted large and significant World Heritage Sites. The Jiuzhaigou Valley Scenic and Historic Interest Area World Heritage Site was nominated for its unique natural and cultural landscapes and traditional Tibetan villages that are representative of the site's cultural heritage. In 2016, more than 7.2 million people visited the county – with 5 million of them going to the site – generating over 9 billion yuan (USD$1.3 billion) in revenue (Leng 2017). Local tour operators are concerned as to how much their businesses will be affected by future natural disasters. The Mount Qingcheng and the Dujiangyan Irrigation System World Heritage Site contains the 2000-year-old Erwang Temple complex which suffered structural damage to its entrance gate, shrines, halls, and artifacts. Restoration efforts have stabilized the site and maintained its representative cultural heritage elements. There are, however, ongoing concerns about the sites experiencing more frequent and severe earthquakes.

Looting

Cultural heritage resources in China, particularly remote areas, are often at risk. This is due to the over hundreds of thousands of monuments, temples, tombs, relics, and artifacts across China, their significant intrinsic value within and outside of the country, and varying degree of control and management. In 2003, more than 220,000 Chinese tombs were broken into and looted, with much of the content being smuggled out of China for sale on the international market (Beech 2003). Taking soil or bricks from the Great Wall – for use in home-building or sale on the black market – has contributed to its deterioration. As a result, whole sections of the World Heritage Site have large gaping holes and are crumbling. The State Council issued a regulation in September 2006 banning vandalism and driving on the Great Wall, and

SACH announced that regular inspections and random checks would be carried out (Moore 2011). The emptying and cleaning of a Henan Province section of the 1,240 mile Grand Canal in 2016, though necessary for health and sanitary reasons, exposed the canal bed. Relics and coins dating back thousands of years quickly disappeared as residents dug up and pocketed ancient treasures (Williams 2016).

Future Directions

China is ranked as the leading country in the world when it comes to having the economy that most values its cultural resources, according to the World Economic Forum's *Travel and Tourism Competitiveness Report 2017* (World Economic Forum 2017). Chinese officials have responded to domestic concerns about the loss of its cultural heritage, particularly in large urban centers affected by development. The Chinese government is also consolidating its World Heritage ambitions to better align with its internal and external economic development policies.

In Beijing, the preparation and convening of international events such as the 2008 Summer Olympics witnessed the removal of traditional hutong communities and displacement of residents. Responding to concerns about continuous loss of the city's historic fabric, on September 2017, the Central Committee of the Communist Party of China and the State Council approved the general city plan for Beijing 2016–2035. The intent is to create a world-class harmonious and livable city, capping the population at 23 million by 2020 (Deng and Jie 2017). There was also a pledge to reinforce that the historic city should not be further demolished and enforce protection of the "Three Hills and Five Gardens" section of the city in Haidian District, where imperial palaces and gardens (incorporating the Summer Palace World Heritage Site) are located (Central Committee of the Communist Party of China 2017). To consolidate the sites in the city's historic core, the Chinese government does have the Central Axis of Beijing (including Beihai) listed on its Tentative World Heritage site list. The 7.8-km-long Central Axis is viewed as a unique historical tableau, ingeniously organizing the imperial places and city, temples and altars, markets, and streets from feudal times to the Tiananmen Square complex built after the founding of the People's Republic of China in 1949 (UNESCO 2017a).

On a national scale, the Chinese government considers new listings on the World Heritage List as an important application of "soft power" to reinforce the country's international stature (Wang and Zan 2011). One of the country's principal economic development drivers being developed is its Belt and Road Initiative (BRI). Chinese leader Xi Jinping advocated in 2013 for the contiguous economic integration of Central and Southeast Asia through the construction of infrastructure, increasing cultural exchanges, and expanding trade (Wang and Lu 2016). There is an intent to consolidate the components of the Silk Road and the Maritime Silk Route on a World Heritage basis. The Qin Terracotta Warriors and Horses in Xi'an, the land route's eastern nexus, and the more recent Silk Roads: The Routes Network of Chang'an-Tianshan Corridor in 2014 are the current main route components on the World Heritage List. The Chinese section of the Silk Road is on the Tentative List and links 63 sites in the land and maritime routes, stretching between Xinjiang and Fujian provinces. This route will eventually be connected with other proposed Silk Route World Heritage projects coursing through Bhutan, India, Iran, Kazakhstan, Kyrgyzstan, Nepal, Pakistan, Tajikistan, Turkey, Turkmenistan, and Uzbekistan (UNESCO 2015). These Silk Road corridors may eventually combine 500 sites across the region under the World Heritage and BRI banners, resulting in the most ambitious and expansive international cooperation program for heritage preservation and archaeology ever undertaken (Winter 2016).

China: Domestic Archaeological Heritage Management Law

Amanda Kate Maus Stephen
Amanda Kate Maus Stephen, Juris Doctor
Kenmore, WA, USA
School of Management, City University of Seattle, Seattle, WA, USA

Introduction

China is commonly referred to as a source country, meaning it is rich in cultural art and

property, but poor in terms of economic resources. Many source countries face intense demand for their cultural relics, resulting in increased illicit excavation. Unfortunately, the impact of illicit excavation on archaeology can be devastating. When items are excavated without regard for the integrity of the original site, much information about the item, its use, and its historical context can be lost (He Shuzhong 2001). With more than 7000 years of cultural history, the People's Republic of China has an immense number of important archaeological sites and a growing need for help preserving those sites.

Illicit excavation is not the only archaeological problem China faces. Interest in China's history fuels tourism demands, as well. In the past, it was not uncommon for local towns or provinces to move archaeological sites or structures in their entirety to places more easily accessible by tourists (He Shuzhong 2001). When not done properly, this resulted in a loss of the integrity of the original archaeological sites.

Culturally significant items protected by law are referred to as "cultural relics" in China's legislation. In order to protect these cultural relics, China has promulgated several important domestic laws including the Regulations of the People's Republic of China Concerning the Administration of the Work for the Protection of Underwater Cultural Relics (Regulations on Underwater Cultural Relics), Measures of the People's Republic of China for the Administration of the Foreign-related Archaeological Activities (Measures for Archaeological Activities), and the Law of the People's Republic of China on Protection of Cultural Relics (the Cultural Relics Law). China has also become a signatory to several international agreements, including the 1970 United Nations Educational, Scientific, and Cultural Organization ("UNESCO") Convention to Prohibit the Illicit Import and Export of Cultural Property and the 1995 International Institute for the Unification of Private Law ("UNIDROIT") Convention on Stolen or Illegally Exported Cultural Objects. This entry focuses exclusively on China's domestic legislative regime.

Definitions

China's legal framework and its legislation protecting cultural relics are protective and nationalistic. Its strict rules are reflective of the overall goal of all of China's domestic policies: legitimization of the communist regime (Murphy 2009). By comprehensively limiting the cultural relic activities within its borders, the communist government is able to showcase both its dominance to outsiders and its willingness to protect the country's treasures to its citizens. China's status as a source nation may also contribute to its instinct to foster greater protection for its cultural relics (Maus 2009).

This protectionist theme is especially evident in the Cultural Relics Law's definition of "cultural relics." According to the Cultural Relics Law, these include a broad spectrum of things:

1. Sites of ancient culture, ancient tombs, ancient architectural structures, cave temples, stone carvings, and murals that are of historical, artistic, or scientific value
2. Important modern and contemporary historic sites, material objects, and typical buildings that are related to major historical events, revolutionary movements, or famous personalities that are highly memorable or are of great significance for education or for the preservation of historical data
3. Valuable works of art and handicraft articles dating from various historical periods
4. Important documents dating from various historical periods and manuscripts, books and materials, etc. that are of historical, artistic, or scientific value
5. Typical material objects reflecting the social system, social production, or the life of various nationalities in different historical periods

Paleovertebrate and Paleoanthropoid fossils are also protected in the same way as cultural relics.

The Cultural Relics Law distinguishes between "movable" and "immovable" cultural relics. "Immovable" cultural relics include sites of ancient culture, tombs, cave temples, and stone

carvings. These cultural relics are designated for protection at either the national, provincial, city, or county level. "Movable" cultural relics include material objects, art, and documents. These are divided into two categories: valuable cultural relics and ordinary cultural relics. Valuable cultural relics are further subdivided into grade-one, grade-two, and grade-three cultural relics. These classifications are used for various reporting, export, and import requirements.

The Measures for Archaeological Activities, promulgated in 1991, provides definitions of "archaeological investigations," "explorations," "excavation," and "recording." These definitions are also extremely broad. Archaeological investigations include activities conducted for the purpose of obtaining archaeological materials and information, such as the recording of ancient cultural sites, ancient tombs, ancient architectures, cave temples, and underground or underwater cultural relics and collecting cultural relics and natural specimens. Archaeological explorations include activities aimed at obtaining information about the nature, structure, and range of underground or underwater historical cultural remains. Archaeological excavations include activities conducted to obtain archaeological materials and information, archaeological recordings, and cultural relics and natural specimens. Finally, archaeological records are systematic activities such as writing descriptions, surveying, cartographing, rubbing, photographing, cinematographing, and videotaping.

Historical Background

Traditionally, cultural heritage and archaeological sites were widely respected by the Chinese people because they were thought of as the "soul of the ancestor" (He Shuzhong 2001). In 1950, China adopted rules on the export of cultural heritage objects, and in 1961, it adopted regulations on the protection of those objects (He Shuzhong 2001). But, during the "Cultural Revolution" from 1966 to 1976, loyalty to authority and respect for the past were branded foolish concepts, and many Chinese adopted this attitude (He Shuzhong 2001).

In 1978, China adopted a "Reform and Opening" policy where the country was opened up to foreign investment and travel. As a result of the influx of foreign money and tourists, the market for Chinese cultural relics boomed. Widespread poverty and a general lack of reverence for national cultural heritage following the "Cultural Revolution" prompted many Chinese citizens to take advantage of the valuable cultural relics that were, literally, in their own backyards. Relics in homes, yards, museums, and archaeological sites were pillaged and sold to eager foreigners, who often were able to resell the objects at a much higher price abroad.

Recognizing that its cultural relics needed additional protections, China promulgated the Law on the Protection of Cultural Relics in 1982 ("1982 Law"). This law was the first authoritative source of protection for Chinese cultural relics. Although of great general benefit, one of the law's weaknesses was that it did not clearly delegate responsibility between the national government and the regional municipalities because such responsibility was based on the rarity and value of the relic under consideration (Maus 2009). In addition, all cultural relics were deemed owned by China. The law did not allow citizens to acquire private ownership of any cultural relics, including those inherited from family members or purchased from stores and at auction (Maus 2009). As a result, there was little incentive for Chinese citizens to comply with the law if the benefit of ownership of relics held or discovered went only to the government. The 1982 Law was amended in 1988 and 1991 and eventually repealed with the passage of the Cultural Relics Law in 2002.

Key Issues/Current Debates

Current Laws Protecting Cultural Relics

The Cultural Relics Law (as amended in 2007, 2013, and 2015) provides broad rules for the protection of both moveable and immovable cultural relics. Although it does require that many immovable cultural relics and all relics remaining underground or in China's waters belong to China, it also provides some mechanisms for individuals to obtain legal ownership of cultural

relics. Although individuals may not own illegally obtained cultural relics, the Cultural Relics Law provides "moral encouragement or material awards" to be provided to those who are diligent in implementing the law, fighting criminal acts under the law, donating important cultural relics, reporting discovered cultural relics, contributing to archaeological investigations or the science of protection techniques, rescuing cultural relics, or making outstanding achievements in work concerning cultural relics. The Cultural Relics Law also allows for the establishment of cultural relic stores and auction houses to be opened, subject to approval by the administrative department for cultural relics under the State Council. Private owners of cultural relics are still subject to the protection requirements of the Cultural Relics Law.

The national government body responsible for overseeing cultural relic protection is the administrative department for cultural relics under the State Council, China's national government. Additionally, local governments are responsible for the administration of the Cultural Relics Law at their respective levels.

Immovable cultural relics must be verified and announced by the respective national, provincial, county, or city government responsible for them. Cities, towns, neighborhoods, and villages with an unusual wealth of cultural relics may be designated for their protection in their entirety. The local governments are then responsible for implementing plans to protect the historical relics, put up signs and notices recognizing the relics, establish records and files about the protected relics, and assign organs or individuals to be responsible for the relics. Construction plans that will affect cultural relics must include protective measures in consultation with the departments for urban and rural construction planning and the administrative departments for cultural relics. Deformation and pollution of protected sites is prohibited. And, while no construction is allowed within a protected area generally, approval for exceptions can be obtained from the governmental entity responsible for the area's protection. Similarly, where it is impossible to protect the relic's original site or the relic needs to be moved to avoid damage, approval is required. Expenses incurred in complying with these rules are borne by the entity in charge of construction.

Any necessary repairs to immovable cultural relics are subject to approval. Immovable cultural relics owned by the State may not be transferred or mortgaged to anyone. If the immovable cultural relic is owned by an individual, it may not be transferred or mortgaged to foreigners. Furthermore, any transfers or mortgages to citizens must be reported to the appropriate government level.

Museums, libraries, and other institutions with cultural relics must classify the relics in their possession according to grade, compile files for the relics, establish a strict system of control, and submit this information to the appropriate administrative department of cultural relics. These institutions are also required to enhance publicity and education of China's cultural heritage by holding exhibitions and conducting scientific research regarding the relics in their possession. They must install mechanisms to protect all relics against fire, robbery, and natural disasters. Institutions are prohibited from donating, leasing, or selling relics in their collections to other entities or individuals. When relics in a collection are damaged, stolen, or missing, such matters must be reported to the appropriate administrative department for cultural relics.

Generally, no state-owned cultural relics or privately-owned valuable cultural relics may leave China, although special approval may be granted by the State Council. All relics that are removed from China are subject to examination and will be issued an exit permit.

Despite these protections, the Cultural Relics Law has two weaknesses. First, it does not adequately incentivize citizens to return relics that are obtained illegally (Maus 2009). Although, the "moral encouragement or material rewards" may be issued to an individual who discloses illicit excavation, such a vague and unpredictable reward, when compared to the choice of keeping the object for oneself or selling it to an antiquities dealer for a profit, does not encourage citizens to follow the Cultural Relics Law (Maus 2009). Also, although the Cultural Relics Law requires entities and individuals in possession of cultural

relics to perform specific duties, it does not provide specific funding for such activities (Maus 2009). The law vaguely requires that the governments incorporate cultural relic protection into their budgets and that revenue from museums and other cultural sites be directed to relic protection (Maus 2009). But, it does not guarantee any funds for cultural relic protection.

In 2003, the State Council adopted regulations for the implementation of the Cultural Relics Law. These Regulations, revised in 2013 and 2016, supplement the Cultural Relics Law, explaining how funds for the protection of cultural relics can be spent, the content of signs and notices for immovable cultural relics, the required content of records and files kept on cultural relics, and how a person becomes qualified to repair cultural relics. It also provides details for cultural institutions regarding how cultural relics should be recorded and tracked; how to gain approval for repairs, duplication, rubbings, and photographs of cultural relics; what to do if cultural relics are stolen or go missing; and legal liabilities for those involved with cultural relics. The Regulations provide specific instructions for individuals who own cultural relics, as well as information for how an entity can apply to become a cultural relic store or a cultural relic auction house. Finally, the Regulations provide detailed instructions about the entry and exit of cultural relics to and from China.

China's Ministry of Culture has also established regulations and rules related to cultural relic protection. In 2005, it promulgated the Provisional Regulations on the Procedures for Cultural Heritage Administrative Penalties. These regulations name the Cultural Heritage Administrative Department of the State Council as the national body in charge of administrative penalty cases, establish procedures and fines for different infractions, and set forth a hierarchy of penalty administration within the different levels of government (Bell 2016). In 2009, the Ministry of Culture also issued Provisional Measures on the Recognition and Administration of Cultural Relics. These measures provide guidance about the recognition and rating of cultural relics by the government.

Finally, in 2013 the Ministry of Finance and the State Administration of Cultural Heritage promulgated the Measures for the Administration of Special Subsidy Funds to the Protection of Key National Cultural Relics. The purpose of these measures is to regulate and strengthen the management and use efficiency of special subsidy funds designated for the protection of cultural relics.

Underwater cultural relics are specifically protected since 1989 by the Regulations on Underwater Cultural Relics, which was revised in 2011. The regulations define underwater cultural relics as human cultural heritage that has historic, artistic, and scientific values and remain in the Chinese inland waters, Chinese territorial waters, waters under Chinese jurisdiction, and in the high seas. But, the regulations do not protect relics that are not associated with important historical events, revolutionary movements, or renowned personages and have remained underwater since 1911.

Similar to the Cultural Relics Law, the Regulations on Underwater Cultural Relics designate the State Administration for Protection of Cultural Relics as the competent authority in charge of the registration of underwater cultural relics, the administration of their protection, and examination and approval of archaeological activities concerning such relics. Also similar to the Cultural Relics Law, activities that may jeopardize the safety of underwater cultural relics are prohibited, discovery of underwater cultural relics must be reported and handed over to the State promptly, and approval is needed to conduct archaeological exploration and excavation activities.

Current Laws Regarding Archaeological Investigations

In 1991, the State Bureau of Cultural Relics promulgated the Measures for Archaeological Activities. Under these measures, any archaeological investigations by a foreign group must be undertaken in collaboration with a Chinese team, and the Chinese team members must be in charge. The State Bureau of Cultural Relics is in charge of the administration of all foreign-related archaeological investigations. Parties wishing to conduct an investigation must submit a written application to the Bureau, and the investigation must satisfy certain conditions described in the measures.

Any data obtained must be collected in a report, and the Chinese experts in the group have first priority for publication of the findings. Any relics or specimens obtained are owned by China but can be transported out of China with permission. Approval is needed for students and others visiting archaeological sites, and investigations are subject to inspection by the Bureau. Warnings or other penalties may result for violations of these measures.

The Cultural Relics Law provides several additional rules about archaeological activities. Many of the measures described above are incorporated into the Cultural Relics Law, but the law focuses on excavations as a result of construction or impromptu excavations when relics are found. It also allows for a small amount of relics to be kept for scientific study.

Current Penalties for Illicit Excavation

There are strict penalties for those who illegally excavate cultural relics and violate the current laws regulating cultural relics. Both Chapter 7 of the Cultural Relics Law and the 1997 Criminal Law ("Criminal Law") provide such penalties.

Under the Cultural Relics Law, anyone caught illegally excavating relics, intentionally or negligently damaging or destroying valuable relics, selling or giving away relics without authorization, smuggling relics, robbing, plundering or privately dividing relics, or hindering the State's control over relics will be criminally investigated. Civil penalties will be imposed on individuals who cause a relic to go missing or damage a relic. Individuals who act against the security administration or smuggle relics will be subject to the relevant laws and administrative rules and regulations of the security administration or customs. Fines may be assessed for less serious violations of the law. Serious violations, such as conducting construction projects within a protected area, removing or dismantling immovable cultural relics, or repairing cultural relics without approval, may result in the entity or individual losing any certificate issued to perform such work.

There are also penalties for polluting a cultural relic site. Where the layout, environment, or historical features of a town, neighborhood, or village of cultural value are undermined, the State council will revoke that municipality's special designation as a city of cultural importance.

Cultural relic stores, auction enterprises, and cultural relic institutions that engage in prohibited activities may have their licenses revoked, depending on the severity of the circumstances. Failures to comply with various reporting requirements in the Cultural Relics Law will require the offending individual or entity to make the omission right by complying with the provisions violated.

Finally, individuals working for the administrative department for cultural relics, an institution for the collection of cultural relics, a cultural relic store, or a cultural relic auction enterprise and who violate the Cultural Relics Law will be assessed an administrative penalty and may also face termination, depending on the severity of their offense.

Like the Cultural Relics Law, the Criminal Law provides various punishments, ranging in severity from fines to prison sentences, for individuals who vandalize, destroy, steal, or illegally export, sell, or excavate cultural relics (Maus 2009). The Supreme People's Court and the Supreme People's Procuratorate issued an Interpretation on Several Issues Concerning the Application of Law in the Handling of Criminal Cases Concerning Hampering the Administration of Cultural Relics, which became effective in January 2016. The interpretation states that individuals convicted of cultural relic crimes will be prosecuted and sentenced based upon the grade of the cultural relics at issue and provides specific guidance for each grade of relic.

In recent years, China has sent a clear message to violators of the law by forcefully prosecuting violators. For example, in 2015 the government convicted 30 defendants of stealing cultural relics from the Hongshan cultural relic protection region, with sentences ranging from 3 years to life imprisonment (China Daily 2016). When originally promulgated, some violations of the Cultural Relics Law were punishable by death, and in 2002, China sentenced four individuals to death for using explosives and heavy machinery to plunder 2500-year-old tombs (CBS News 2010). But, in 2011, China revised the criminal

law to reduce the number of crimes punishable by death, cultural relic offenses being among those (China Daily 2011).

International Perspectives

Opinions about China's legislative protection of cultural relics are mixed in the United States. Criticisms of China's measures were openly and widely discussed, while the United States was considering whether to adopt an international agreement with China under the UNESCO Convention. In 2004, China requested that the United States sign an agreement to restrict the importation of all ethnological and cultural artifacts dated before 1911, in order to discourage smugglers from transporting such items into the United States (Maus 2009). The agreement was adopted with modification in 2009 (Marton 2009). The Memorandum of Understanding (MOU) adopted by the United States and China restricts the US import of Chinese antiquities dating from the Paleolithic Period to the end of the Tang Dynasty and monumental Chinese sculpture and wall art that is at least 250 years old (Marton 2009). In 2014, the agreement was extended for an additional 5 years (Huo 2015).

The United States' delay in responding to China's initial request was unusual (Maus 2009). Suspected reasons for the delay include China's failure to adequately control its domestic illicit relic trade, as well as its perceived failure to enforce its current laws, such as the Cultural Relics Law or the Criminal Law (Maus 2009). Additionally, although illicit excavation is a serious problem in China, many more relics are unearthed as a result of building and road construction (Marton 2009). Many scholars in the United States believe that China values its economic growth and industrialization over its commitment to protecting cultural relics (Murphy 2009). Finally, funding of cultural relic protection is a major issue in China. It is generally understood that all cultural protection activities are underfunded and that the lack of funding negatively impacts enforcement of the laws currently in place (Marton 2009). Many in the international community believe that China must commit additional funding to its protection efforts before illicit excavation can be meaningfully curbed (Maus 2009; Huo 2015).

Future Directions

China's cultural relic legislation is admirable and sends a strong message both domestically and abroad that the State values its cultural heritage and wants to protect it. However, going forward, China will have to square this policy with its sometimes antithetical policy of development. Some scholars believe that the Chinese government at all levels largely looks the other way when commercial development construction projects threaten to violate the cultural relics laws (Murphy 2009; Maus 2009; Baskin 2009). Additionally, in recent years, the import of cultural property into China has allowed China to grow into the world's second largest market country, meaning it is not simply a source nation (Huo 2015). Because the Cultural Relics Law does not provide any import restrictions, some scholars believe that reform of the law to address imports is necessary (Huo 2015). Essentially, if China wants the international community to respect its domestic legislation and requests for repatriation of cultural relics, it must show that its relics garner the same level of respect within its own boarders.

There is no doubt that China takes its responsibility to protect its cultural relics very seriously and is taking actions toward a more stringent protection regime. In September 2017, the State Council issued a guideline acknowledging that there has been frequent illegal dealing, storing, and auctioning of cultural relics in recent years, displaying a lack of supervision and loopholes in protection work (China Legal Information Center 2017). The guideline reiterated that all levels of government should strengthen law enforcement protection of cultural relics and fulfill their respective duties in the management and security of cultural relics (China Legal Information Center 2017).

On a more positive note, China may be opening to educational and archaeological studies by

foreigners. Although the Cultural Relics Law and the Measures for Foreign-related Archaeological Activities greatly restrict archaeological and educational opportunities for foreigners in China, the MOU signed with the United States may relieve some of red tape faced by foreigners. In the MOU, China agreed to two important provisions. First, it agreed to promote the exchange of students and professionals in such fields as archaeology, art history, conservation, museum curatorial practices, and cultural heritage management between appropriate Chinese and US institutions (Hoffman 2010). Additionally, it agreed to facilitate the granting of permits to conduct archaeological research in China (Hoffman 2010). For students and scholars in the field of archaeology and related disciplines, this may mean greater access to the treasures of China's past.

China: Managing Cultural Heritage and the World Heritage List

Wei Zhao
School of Architecture, University of Illinois at Urbana-Champaign, Champaign, IL, USA

Introduction and Definition

The World Heritage Convention was adopted by the General Conference of UNESCO at its 17th session in Paris on November 16, 1972. It concerns the protection of the World Cultural and Natural Heritage. China ratified the World Heritage Convention on December 12, 1985. As of 2012, there are 30 cultural sites, 9 natural sites, and 4 mixed sites in China that were inscribed on the World Heritage List (Fig. 1).

China established its own cultural and natural heritage classification and management system before it signed the UNESCO World Heritage Convention. There are eight major categories in China's classificatory scheme, including historic structures and other non-movable relics, movable cultural relics, historic cities, historic towns, historic villages, national parks, intangible cultural

then to the departments. However, the so-called organizations and administrations and bureaus are between the levels of ministry and department, yet have different administrative independence. The administrations and bureaus, even though they are directly under the State Council and operate independently, are managed by the corresponding ministries. Therefore, they are not as independent as the offices under the category of "organizations," nor do they have the same power; the heads of these offices, therefore, might have a slightly lower official ranking than the ones in charge of the "organizations." For example, the State Administration of Cultural Heritage and the State Administration of Grain belong to "administrations and bureaus," while the National Tourism Administration and the State Forestry Administration are categorized as "organizations."

For the administrative hierarchy of local governments, the provincial level is the one directly beneath the central government. The following levels (discussed in this study) are county, town, and village. "City" itself does not represent an administrative hierarchy, since cities could be categorized into multiple levels. It could be in the provincial level, such as Beijing and Shanghai; it could be in the regional level (in between the provincial and county levels), such as Chengde and Suzhou mentioned in the World Heritage List; it also could be in the county level, such as Dujiangyan and Dunhuang (importantly, this is where the World Heritage Site of Mogao Caves is located).

Historical Background

Heritage Management

The State Administration of Cultural Heritage is directly under the State Council and is managed by the Ministry of Culture. It is legally in charge of the administration of historic structures and other non-movable relics, as well as movable cultural relics. Note that *relic* is the word used in China for ancient remains. There are seven subcategories under the rubric of historic structures and non-movable relics: archaeological sites, ancient tombs, historic buildings, religious grottos, stone carvings, frescos, and sites and buildings that are related to historical events and revolutions in modern (since 1840) and contemporary Chinese history. There are three classes of relics: national cultural relics, provincial cultural relics, and city or county cultural relics, which represent various levels of importance. Movable cultural relics include artifacts, artworks, documents, manuscripts, and books. These are classified as either valuable cultural relics or ordinary cultural relics. Valuable cultural relics are further divided into grade-one, grade-two, and grade-three cultural relics. For the purpose of this entry, only the historic structures and non-movable relics that are classified as national cultural relics are included.

The State Council announced the first group of national cultural relics in 1961, after the completion of the first nationwide investigation and assessment of cultural relics by the State Administration of Cultural Heritage in the late 1950s. There are a total of 180 sites, which include 77 historic buildings, 33 revolutionary monuments and memorials, 26 archaeological sites, 19 ancient tombs, 14 religious grottos, and 11 stone carvings. More sites were subsequently added: 62 sites in 1982, 258 sites in 1988, 250 in 1996, 518 in 2001, and 1080 in 2006. Currently, there are a total of 2,351 national cultural relics. (Two sites in the first group were combined into one in 2001; three sites were later added into the 2001 list; one site was later added into the 2006 list. "National Cultural Relics," *Baidu*, accessed on December 4, 2010, http://baike.baidu.com/view/163959.html). In general, the buildings and sites listed in the earlier dates might have higher cultural, historical, or artistic value than those added later, except for the potential new discovery of exceptional archaeological sites. Additionally, it is important to note that there is an increasing attention to vernacular architecture and its built environments.

In April 2007, the State Council announced the beginning of the third nationwide investigation and assessment of cultural relics, which was scheduled to be complete in December 2011. The question, then, is how many more sites will be added to the already very long list – an issue

relevant to UNESCO's World Heritage List, which itself is nearing 1,000 inscriptions.

The Department of Urban–rural Planning, directly under the Ministry of Housing and Urban–rural Development, is responsible for the assessment, preservation, supervision, and management of the historic cities. Twenty-four historic cities were included in the first group announced by the State Council in 1982; 36 were added in 1986; 37 were added in 1994; another 12 cities were added between 2001 and 2010. This makes a total of 112 historic cities in China. Historic towns and historic neighborhoods are managed by provincial offices.

Another department under the Ministry of Housing and Urban–rural Development is the Department of City Development, which manages the National Park of China (also referred to as National Tourist Scenic Spots on earlier application dossiers for World Heritage Sites). The National Park of China includes sites with both natural beauty and historic built environments. It was created in 1982 with 44 sites and amended six times in the following years: 40 additional sites were added in 1988, 35 in 1994, 32 in 2002, 26 in 2004, 10 in 2005, and 21 in 2009. Currently, there are 208 national parks recognized by the state.

Since 2003, the Department of Urban–rural Planning, under the Ministry of Housing and Urban–rural Development, with the assistance of the State Administration of Cultural Heritage, started two new programs to evaluate historic towns and villages that have historical importance or that represent the traditional culture or character of a local ethnic group. Ten towns and 12 villages received the title of National Historic Towns and National Historic Villages in 2003, an additional 34 towns and 24 villages in 2005, 41 towns and 36 villages in 2007, 58 towns and 36 villages in 2008 and 2009, and 38 towns and 61 villages in 2010. Currently, there are 181 national historic towns and 169 national historic villages.

Obviously, buildings or structures can be part of a cultural relic, historic city, historic town, historic village, or national park. Therefore, they could be subject to the administration of three different offices. However, in terms of their approaches to cultural heritage, the essential difference between the State Administration of Cultural Heritage and the Ministry of Housing and Urban–rural Development is clear. The former handles only singular buildings or building groups in isolation, while the latter extends its focus to large built environments and landscapes.

The first group of national cultural relics was announced in 1961, while the initial lists of national historic cities and national parks were created 21 years later in 1982. The concept of protecting an entire historic city (meaning that it has been continuously occupied) is a new approach in preserving cultural relics. The idea was generated by three scholars: Renzhi Hou (historical geographer), Xiaoxie Zheng (urban planner), and Shiyuan Shan (architect in historic preservation). It is difficult to judge how much of their idea was influenced by preservation theory and practice worldwide, inasmuch as China's economic reform started in 1978, a couple of years before the rise of this new concept.

The division between the singular building in isolation and the overall consideration of the built environment has the potential to create many problems during the process of preservation. The fact that these two types of heritage are managed by three different offices, under two different ministries, can cause difficulties in terms of administration and management. This division becomes more complicated following China's signing of the UNESCO World Heritage Convention. Currently, the State Administration of Cultural Heritage is responsible for nominating and managing the cultural World Heritage Sites; the Department of City Development (the office that also manages the National Parks of China), under the Ministry of Housing and Urban–rural Development, is in charge of nominating and managing the natural and mixed World Heritage Sites. The Department of Urban–rural Planning (which manages the Historic Cities), under the Ministry of Housing and Urban–rural Development, and the State Forestry Administration (which manages the National Natural Reserves) are left alone in this process.

The process of assessing and then nominating sites (by means of the Tentative List) to the World Heritage List should involve discussion with other departments, since the process of enlisting the

National Parks of China usually includes eight departments. However, the department holding the ultimate responsibility is the one that takes the lead in organizing the procedure, as well as making the final decision. This might explain why the first 17 and the last 4 of the 53 sites on the Tentative List, arranged chronologically, are either natural sites or mixed sites, which are in relation to the National Natural Reserves and National Parks of China, respectively. In the meantime, out of the other 32 sites, all listed in the year of 2008, there is only 1 mixed site as an extension project of an existing mixed World Heritage Site; the remaining 31 sites are all cultural sites, including the Hani Terraces (the stepped rice terrace) that might be better described as a cultural landscape. For the World Heritage Sites, all four mixed sites and the first four listed natural sites hold the title of National Parks of China. It seems that these two offices have taken the lead in nominating World Heritage Sites in turns. It might not be their intention to only nominate the sites under their own administration, but they might simply not have enough information about other sites managed by other departments. Therefore, the fact that the department managing the historic cities has not been directly involved in nominating and assessing sites for the World Heritage List has a huge impact on the components of this list. Xi'an, which is one of the four most important historic cities of China – the others are Beijing, Nanjing, and Luoyang – (and surely should be inscribed on the World Heritage List) and which received the title of Historic City in 1982, does not even appear on the long Tentative List. Furthermore, only 2 out of the 32 World Heritage Sites (cultural and mixed sites) in China are historic cities or districts in mainland China (The Historic Centre of Macao, inscribed in 2005, may be managed by a different office and through a special procedure since Macao is officially designated as a "special administrative region").

Administrative Independence and Responsibility of the State Administration of Cultural Heritage

The State Administration of Cultural Heritage is the office that directly supervises 28 of the 32 nonnatural World Heritage Sites in China and also enforces China's heritage law. (The law can be read at this website: http://www.sach.gov.cn/tabid/311/InfoID/383/Default.aspx [this is the official address under the State Administration of Cultural Heritage]). Therefore, only this office, as well as its administrative independence and responsibility, is considered here.

The hierarchical relationship (impacting the level of administrative independence and responsibility) between the Ministry of Culture and the State Administration of Cultural Heritage has been changed and constantly redefined many times since being founded in 1949. The predecessor of the State Administration of Cultural Heritage is the Department of Cultural Heritage, which was founded in 1949. In the following 17 years until the Cultural Revolution started in 1966, the responsibility of the Department of Cultural Heritage changed many times; it was once in charge not only of cultural heritage and museums but also libraries, cultural centers, and long-distance education. In 1973, the Department of Cultural Heritage became the State Administration of Cultural Heritage, directly under the State Council. In 1982, it, along with four other departments, formed the new Ministry of Culture in 1982. In 1988, 3 years after China signed the World Heritage Convention, the same department with the same responsibilities once more became the State Administration of Cultural Heritage and started to report directly to the State Council. Its administrative independence appears to have remained the same since then. This department is directly under the State Council but is being managed by the Ministry of Culture. It operates independently and has its own schedules, budgets, and supplies.

The major responsibility of the State Administration of Cultural Heritage can be briefly summarized into the following categories, which include implementing cultural heritage law and enacting detailed regulations, managing the national cultural heritage, providing assistance to corresponding offices in case of heritage-related crime, assisting and supervising all the museums in serving the general public and sharing information, arranging and assessing related research projects, administrating training and professional

development, and organizing information and cultural exchange with entities outside China. More specifically, there are detailed responsibilities in managing the cultural heritage. The State Administration of Cultural Heritage is required to establish the standards and procedures for assessing cultural heritage, manage and supervise the World Heritage Cultural Sites, assist the corresponding offices in assessing the World Heritage Natural and Mixed Sites and in managing and preserving the historic cities, organize the nationwide investigation and assessment of cultural relics, inspect and approve preservation plans and new constructions within the protected area of national cultural relics, assess and approve archaeological excavation, and approve the transfer and lending of certain national cultural relics within or outside the country.

Heritage Law: The Primary Law

The *Law of the Peoples Republic of China on Protection of Cultural Relics* is China's primary heritage law. It was initially adopted in 1982; Article 30 and Article 31 were revised in 1991. A revision of the heritage law was finalized on October 28, 2002. The current version was approved by the Standing Committee of the Seventh National People's Congress and signed by the president.

The law has seven chapters. These include general provisions, immovable cultural relics, archaeological excavations, cultural relics in state collections, cultural relics in private collections, transporting cultural relics across the national border, legal liabilities, and supplementary provisions. Here I consider critical points of the law within each chapter.

Chapter One

Chapter one lays out the general provisions. It first states the purpose of establishing this law and the kinds of cultural heritage that are protected by the state and the law. Importantly, one of the purposes of this law is to promote the tradition of patriotism; therefore, one of the five categories of cultural heritage that receives protection by the state is dedicated to sites, objects, and buildings associated with historical events, revolutions, and noted individuals in modern and contemporary Chinese history. It is also notable that the law places emphasis on protecting cultural heritage from all time periods in history. Besides grand architecture and beautiful art works, the law also encompasses preservation of typical objects representing the daily life of all ethnic groups throughout China's history. The law then regulates the classification of cultural heritage (discussed earlier in this entry).

Chapter one also explains the ownership of cultural heritage. The state owns everything within the national border, either buried in the ground or in the water; the state owns all the archaeological sites and most of the historic building except privately owned buildings, which, in most cases, are houses. The law does protect privately owned heritage, but owners are obligated to obey all the heritage law and regulations.

Article 10 not only requires that all local governments that are higher than the county level have dedicated budgets for heritage preservation but also states that the central government will increase the national level budget for heritage preservation according to income.

Article 10 also states that the institutional income of state-owned museums, memorials, and cultural heritage sites shall be exclusively used for the protection of cultural heritage. Article 3 of the *Regulations for the Implementation of the Law of the Peoples Republic of China on Protection of Cultural Relics* further lists how the institutional income can be used. It can be used to store, display, preserve, and collect cultural relics; to renovate and construct the state-owned museums, memorials, and preservation facilities; to safeguard cultural relics; to support archaeological research and excavations; and to support related scientific research and education. The question is what kinds of income are considered institutional income and, therefore, subject to this regulation. It is important to note that the salary and the benefits of the staff are not mentioned here, which could come from the governmental budget, income generated by the institutions themselves, or the combination of these two. As nonprofit organizations, museums, memorials, and cultural heritage sites could have operational

income upon approval. This includes income from collecting entrance fees, as well as gifts shops, restaurants, or lodging facilities. The operational income usually covers the cost for daily maintenance, including salary and benefits for the staff. In some cases, the operational income needs to be turned in to the appropriate governmental office in charge. Clearly, the use and distribution of the operational income is not subject to heritage law or regulation; the amount of money visitors pay is not necessarily used to protect the heritage. When the operational income of a heritage site is directly associated with the staff members' salary and benefits, this nonprofit institution would be no different than a commercial enterprise. This is when the heritage status might be threatened due to neglect, a situation well known around the world.

Chapter Two

Chapter two focuses on managing and protecting immovable cultural heritage, either state-owned or private-owned, which includes detailed regulations and procedures to follow in heritage preservation. Even though the State Administration of Cultural Heritage is in charge of managing the national level heritage, most of the work and the decisions are carried out by provincial offices, such as archiving, setting up an extended protected area, approving appropriate new construction within the protected area, and assessing restoration. However, the State Administration of Cultural Heritage will make the decision when an immovable national cultural relic needs to be relocated or rebuilt on the original site. When demolishing an element of cultural heritage due to unavoidable new construction, approval is required from the cultural heritage management office at a higher level. For example, only the State Administration of Cultural Heritage can make a decision regarding whether to demolish a cultural heritage of provincial level; the immovable national cultural relics cannot be demolished, except as a special case approved directly by the State Council.

Article 21 is dedicated to the preservation and renovation of immovable cultural heritage. In particular, it states that the owner of the private-owned immovable cultural heritage is obligated for such responsibility. However, the local government at the county level and above shall provide financial help to those who are not financially capable of doing so. The local government shall impose the task of renovation when the heritage is in danger and pursue payment from the owner afterwards, if the owner is financially capable.

Articles 23 and 24 regulate usage of state-owned cultural heritage. State-owned immovable cultural heritage of all levels shall only be used as museums, preservation institutes, or tourist spots. For such a heritage to be used for another purpose, one must obtain approval from the heritage management office at a higher level, as well as approval from the same-level government to which the building is managed by the heritage office to which it belongs. Only the State Council has the right to approve alternative usage of national cultural relics. The law states that state-owned immovable cultural heritage of all levels shall not be transferred or mortgaged or used as assets for business operation.

Article 25 regulates the usage of private-owned cultural heritage. Private-owned immovable cultural heritage of all levels shall not be transferred or mortgaged to foreigners. When transferring, mortgaging, or changing the function of the heritage property, the owner needs to report to the appropriate heritage management office and document the change. The owner needs to get approval in this office only when the local government helped to renovate the heritage previously. This means a private owner of a house that is a national cultural relic can make his house a restaurant, a hotel, or a factory without being assessed and approved by any heritage management office.

When the law was initially written in 1982, there was not a single residential structure listed as a national cultural relic; it seems that being a museum or a tourist spot is the only way for the imperial palaces and tombs to show their historical importance to the general public. It was not until 1988 that the first few empty houses (expropriated by the government during the Cultural Revolution) and the first few living vernacular built environments were listed as national

cultural relics. In recent years, there are more dwellings and built environments being added to the list. Since property ownership is complicated in China, a private dwelling does not necessarily mean a privately owned property, not to mention the different levels of ownership and the separation between ownership of the land and the property itself (there is no privately owned land in China). Therefore, the exact consequences of Article 25 cannot be fully understood without a detailed study.

Chapter Three

Chapter three handles the issues related to archaeological excavation. Only the State Administration of Cultural Heritage has the right to accredit the institutes participating in archaeological excavations and approve any archaeological excavations. An excavation within the protected area of an immovable national cultural relic needs to be approved by the State Council. The institutions that participate in the excavation shall turn over the discoveries to the appropriate museums, libraries, or other institution after archiving the relics. Only with exceptions approved by appropriate heritage management offices or the State Administration of Cultural Heritage can such institutions keep a few specimens for research purposes.

Chapters Four, Five, and Six

Chapters four, five, and six are dedicated to issues related to cultural relics in state collections, cultural relics in private collections, and transporting cultural relics across the national border, respectively. The articles focus on movable cultural relics, which are beyond the scope of this entry.

Chapter Seven

Chapter seven concerns legal liabilities. It lists different kinds of behaviors – either violating the heritage law or harming the cultural heritage – and categorizes them into criminal cases, civil cases, or noncriminal cases. It gives detailed information about what kind of administrative sanction or civil penalty each behavior will receive; the criminal case will be charged with the appropriate criminal law.

Chapter Eight

Chapter eight contains the supplementary provisions, which simply state that this law becomes effective on the date of its promulgation.

More Heritage Laws

In support of the *Law of the Peoples Republic of China on Protection of Cultural Relics*, the State Council promulgated the *Regulations for the Implementation of the Law of the Peoples Republic of China on Protection of Cultural Relics* on May 18, 2003, to be effective on July 1, 2003, which was signed by the prime minister. (All the dates listed here are the dates that each regulation was approved; the effective date of each regulation is usually months later than the approval date.)

Other than the fundamental heritage law and regulations, there are numerous ordinances and regulations promulgated by the central government or local governments. Regulations promulgated by the State Council also include the *Ordinance of Preservation of the Great Wall* (September 20, 2006), the *Ordinance of National Parks of China* (September 6, 2006), the *Ordinance of National Reserves* (September 2, 1994), and the *Regulations for Preserving the Historic Cities, Historic Towns, and Historic Villages* (April 2, 2008). There are 43 regulations promulgated by the Ministry of Culture that are listed under the webpage run by the State Administration of Cultural Heritage, such as *Regulations for the Management of the World Cultural Heritage* (November 14, 2006), the *Interim Regulations for Preserving and Managing the National Intangible Cultural Heritage* (October 25, 2006), and the *Regulations for Museum Management* (December 22, 2005).

Key Issues

Bundling Sites: A New Strategy to Achieve Inscription in the World Heritage List

One of the new phenomena of newly listed World Heritage Sites in China is that one World Heritage Site consists of more than one site and the sites can be quite distant from each other. There are two

reasons for this phenomenon. First, the notion of promoting a site to become a World Heritage Site is a very attractive and popular idea for many people: the *government* who wants to establish a new image of the country with both economic strength and a rich culture; *local officials* who want to use this opportunity to build their resume and to improve the local economy by increasing tourists; the *local people* who are proud of having a World Heritage Site in their hometowns; and the *general public* who enjoy the convenience of traveling to World Heritage Sites without spending a lot of money and time to go outside the country, which is a dream that will never be realized by most Chinese people. Under this general social and cultural background, China is preparing 200 individual projects (not sites) for the World Heritage Tentative List. (See, e.g., State Administration of Cultural Heritage 2010). Considering that one country can only send one project per year, it will take hundreds of years for these 200 projects to become World Heritage Sites. Combining similar ones seems the only feasible approach that can expedite this process. Besides this obvious reason, there is another benefit to bundling sites together: it allows sites that are valuable, yet without exceptional value and quality, to become World Heritage Sites.

There are various kinds of approaches concerning *how* and *what* to bundle together. The first example is the Temple and Cemetery of Confucius and the Kong Family Mansion in Qufu (which should actually be documented as the Temple of Confucius and Cemetery and the Kong Family Mansion in Qufu), listed in 1994. Although the Temple of Confucius and the Kong Family's Mansion are separated in time by over 1,300 years, they are located right next to each other and received the recognition of National Cultural Relic as one site in 1961. The Kong Family's Cemetery is far away; it is where Confucius was buried, as were over 100,000 of his descendants. Therefore, this bundling is reasonable and necessary to understand the value and meaning of the heritage site.

The Classical Gardens of Suzhou, listed in 1997, is another example. There are nine sites composing this World Heritage Site. At the time of application, only four of these nine gardens were honored as National Cultural Relics. Two more gardens were honored in 2001; the three remaining gardens received the title as one of the 1,080 sites in 2006. At that time, there were 34 structures or sites within the city of Suzhou with the title of National Cultural Relic. This is a clear case in which the somewhat valuable, yet not exceptional, sites benefit from being bundled together with the exceptional ones.

The Case of Dengfeng

The most manipulated and constructed nomination is "The Historic Monuments of Dengfeng in 'The Center of Heaven and Earth'," which was honored as a World Heritage Site on August 1, 2010 (State Administration of Cultural Heritage 2010). This "site" includes eight sites or 11 structures and building complexes. These 11 structures and building complexes were built in a time frame covering almost 2,000 years of history, including buildings for ritual, religious, educational, and scientific purposes. The title, "The Center of Heaven and Earth," is a constructed concept that bundles these various buildings and sites together.

Importantly, the same "site" went for the nomination of World Heritage Sites in 2009 and did not achieve its goal. In that nomination, the "site" was named "The Historic Monuments of Mount Song Area." After this experience, the regional heritage management office reflected upon the reasons for the loss, and they perceived a few main reasons. The following are mentioned: in general, the evaluation process of World Heritage Sites is getting more rigorous, especially for a country like China, which already has more than 30 sites listed. Furthermore, Mount Song is one of the mountains included in the project of the Four Sacred Mountains as an Extension of Mt. Taishan, which made UNESCO question the repetition. In the meantime, Mount Wutai was adjusted from a mixed World Heritage Site to a cultural landscape during the final decision-making process of UNESCO convention in 2009, because the aspect of its natural value did not get approved; the project of Mount Song has the potential of encountering a similar problem if it follows the path of Mount Wutai. More importantly, the

concept of using Mount Song as central sacred mountain to connect all the sites is difficult for the World Heritage Committee professionals from different cultural backgrounds to understand and appreciate.

Based on these assessments, the regional management office decided to change the name of this application to "The Historic Monuments of Dengfeng in 'The Center of Heaven and Earth.'" Two major implications can be observed in this change. First, Mount Song is out of the equation, even though all these sites are still located with the area of Mount Song; the change places a clear emphasis on the cultural aspect of the site and leaves its natural value aside. Second, the new name also suggests that the implication and influence of this site covers a much larger area, therefore, as a heritage site, its cultural significance increases.

More importantly, the new application introduced the concept of "The Center of Heaven and Earth": the Chinese counterpart is "天地之中," which means "sky, earth, of, and center," respectfully. The Chinese name suggests a connection with an existing Chinese concept; however, it is manipulated and has a different meaning. The Chinese concept of the "Center of the Earth" (地中) or the "Center of the World" (天下之中) was well developed in ancient China in the beginning of the Western Zhou period (1046–771 BCE) as a political strategy to relocate the new capital of the Western Zhou period to the region previously occupied by another ethnic group (Wang 1990; Gong 1994). The ancient Chinese perceive "天" (sky) as everything above "地" (earth) (Wang 1999). Therefore, the phrase "天下" (literally means under the sky) and the word "地" (earth) are synonymous spatially and conceptually. "天下" also refers to the world, a 2-dimensional earth radiating from the "center."

Although there are debates among scholars regarding where exactly the "Center of the World" was perceived by the ancient Chinese, it is generally acknowledged that Mount Song is located in the region considered as the "Center of the World" by the people of the Western Zhou period and many dynasties afterwards. In the case of renaming a World Heritage nomination, by changing the Chinese from "天下之中" to "天地之中," "天" (sky) becomes an independent concept, instead of something closely associated with the "地" (earth). The English translation, "The Center of Heaven and Earth," pulls them further apart both spatially and conceptually as the "heaven" and the "earth." As a result, the concept of the "center" here can be understood in two ways. It suggests a vertical axis, as the *axis mundi*, that connects the heaven and the earth; it can also be perceived as the space between the heaven and the earth, which is similar to the Western philosophical and religious ideas that put human beings at the center between heaven and earth. Both interpretations are manipulations of a classical Chinese concept; it is an adjustment tailored for the Western perspective, in order to make the World Heritage Committee professionals who evaluate the project easily appreciate this already heavily constructed cultural heritage site.

The following list gives a brief description of each of the 11 structures and groups of buildings that are covered under the umbrella of the "Center of Heaven and Earth." (The number indicates the year it was listed as National Cultural Relic when applicable.)

- Taishi Que (1961), a pair of large stone tablets with engravings, was built in 118 CE and marks the ritual path in front of the Zhongyue Temple.
- Zhongyue Temple (2001) was originally built in 110 BCE and has been rebuilt and enlarged many times throughout history. Its current layout and major buildings are based on the reconstruction during the Qing Dynasty (1644–1912 CE). It was a religious temple holding the imperial sacrificial altar for Mount Song.
- Shaoshi Que (1961) was built between 118 and 123 CE and used to be located in front of the Shaoshi-Shan Temple (destroyed), marking the ritual path.
- Qimu Que (1961), a pair of large stone tablets with engravings, was built in 124 CE used to be located in front of the Qimu Temple (destroyed).

- The 40-m-high Songyue Temple Pagoda (1961) was originally built between 520 and 525 CE, the oldest surviving brick tower in China.
- The Shaolin Temple, a Buddhist temple renowned for its martial arts, was originally found in 495 CE. It has three groups of structures, not all adjacent to each other, included in the World Heritage Site: the Kernel Compound (1963, provincial level only), the Pagoda Forest (1996), and the Chuzu Temple (1996, as one site with the Pagoda Forest).
- Huishan Temple (2001) is a Buddhist temple first built between 471 and 499 CE.
- Songyang Academy of Classical Learning (2001) was originally built between 934 and 936 CE and became one of the four largest study centers in the Song Dynasty (960–1279 CE).
- The Observatory (1961) was originally built between 1276 and 1279, as one of the oldest surviving observatories in China.

There is no doubt that all these structures and buildings have their unique historic and artistic values; the fact that 5 of them were part of the list of the first 180 national cultural relics supported this. However, there is no obvious theme shared by all the sites, since they not only represent different kinds of structures – from stone tablets, to towers, and to buildings – but also serve different functions – from ceremonial structures, to religious structures, to scientific structures, and to cemeteries. The concept of the "Center of Heaven and Earth" was clearly a constructed idea that was superimposed on all these sites so they could be bundled together as one World Heritage Site.

In the meantime, there are 16 sites in the City of Dengfeng that were registered as National Cultural Relics by 2006, the most recent date when the list was modified. The question is why the other seven sites were not included. If a site can become a World Heritage Site first, and then a National Heritage Relic 9 years later (in the case of Classical Gardens of Suzhou), there are definitely significant values for any of these seven sites. Perhaps lacking UNESCO's criterion of OUV (Outstanding Universal Value), we can see the benefit of bundling the sites together, according to the argument made by the regional heritage management office. If a cemetery for monks can be associated with the idea of the "Center of Heaven and Earth," those leftover temples, towers, and religious stone carving sites can as well. If the potential tourist income is one of the driving forces in selecting the sites, which is proven by many precedents, some of these leftover sites should be included as well. The entrance fee to enter the individual Fujian Tulou was increased between 40% and 300% of the original price after being inscribed as a World Heritage Site in 2008. The overall income from the entrance fee of the Ancient City of Ping Yao has increased 40 times since its promotion in 1997. However, according to ctrip.com, the leading website providing tourist service in China, out of the 22 sites recommended for the Mount Song area, Fawang Temple, a national cultural relic, is ranked as the 5th favorite site by the tourists, a much higher position than some of the sites included for the World Heritage Site, especially Huishan Temple, ranked as the 21st site.

Other Cases

The case of the Mount Qingcheng and the Dujiangyan Irrigation System, listed in 2000, had a very different approach. Mount Qingcheng is one of the birthplaces of Taoism with many Taoist temples, while Dujiangyan is an irrigation system built in the third century BCE and still in use. The two sites are in proximity to each other; however, I would argue that their difference should decouple them from being one World Heritage Site.

Another case is the Imperial Tombs of the Ming and Qing Dynasties, which eventually includes eight sites in five provincial jurisdictions. When the site was first listed in 2000, it included two clusters of tombs of the Qing Dynasty in Hebei Province and one tomb of the Ming Dynasty (the Xian Tomb in Hubei Province); the Qing tombs and the Ming tomb received the title of National Cultural Heritage in 1961 and 1988,

respectively. As the only Ming tomb included, the Xian Tomb is not the most famous one in China. There are 13 Ming tombs scattered in the mountain area of Beijing and the Xiao Tomb of Ming, the burial land for the very first emperor of the Ming Dynasty, located in Nanjing, Jiangsu Province; both were honored as National Cultural Relics in 1961. The obvious questions are the following: who organized the application process? Who decided which tombs to include? What were the reasons for the exclusion of the majority of the Ming tombs even though the name of this World Heritage Site suggests collective tombs from the Ming Dynasty? However, this is not the end of the story. The Ming tombs of both Beijing and Jiangsu Province were added as an expansion to the existing World Heritage Site in 2003. Three additional Qing tombs in Liaoning Province were added in 2004. They are the Ancestral Tomb and the tombs for two earlier emperors of the Qing Dynasty, which became the National Cultural Relic sites in 1982 and 1988. I ask whether this World Heritage Site will one day be expanded to include all the imperial tombs in China. (Comparably, will a similar inscription named "Tuscan Hill Towns" be created and include all the hill towns in central Italy?)

Future Directions

China's vast territory, extraordinary history, and exceptional built environment facilitate a large numbers of sites to be nominated to UNESCO's World Heritage List. China's success in bundling sites for evaluation by the World Heritage Committee will inevitably set up a new precedent for the application and packaging of future World Heritage Sites in China. Its potential impact on heritage policy, heritage management, the general public's attitude towards heritage sites, and the tourists' evaluation and preference of heritage sites are yet to be discovered. In the meantime, the direct outcomes of bundling to the sites, their local stakeholders, the Chinese public, and the tourism industry deserve monitoring and studying in the coming years.

China: Museums

Li Hui Dong
Institute for Cultural Heritage, Shandong University, Shandong, P. R. China

Introduction and Definition

Compared to the long written history in China, the word "museum 博物馆 博物馆 (bo-wu-guan)" is quite new: it was introduced to China by the Japanese in the late nineteenth century. In ancient Chinese, "bo-wu" means natural science or a person in command of broad or extensive matters; "guan" refers to places where cultural relics were kept or managed and where knowledge was taught.

Over the past 100 years, the concept of the museum in China has changed from a purely educational organization into one that collects and curates cultural relics and specimens and engages in propaganda and education, and scientific research. The role of museums in China needs to be considered in relation to the definition of the museum adopted by the International Council of Museums (ICOM) at the 21st General Conference in Vienna, Austria, in 2007:

> A museum is a non-profit, permanent institution in the service of society and its development, open to the public, which acquires, conserves, researches, communicates and exhibits the tangible and intangible heritage of humanity and its environment for the purposes of education, study and enjoyment. (ICOM 2012)

In practice, the concept of museum in China is a little different from ICOM's definition. The

main functions of Chinese museums are to inherit and disseminate knowledge of Chinese culture, integrate social and ethnic memories, represent the historical attitudes of the government, and reflect on visual representations of China. Throughout China, governments at various levels invest heavily in museums, not only as a tool for propaganda and public education and for reflection on history but also as a physical symbol of the status and wealth of a particular city or region.

Key Issues

Key issues in Chinese culture can be understood through the lens of the museum, and through an understanding of the changing concept of the museum through time.

Brief History of Chinese Museums

It can be argued that collecting is one of the instincts of human beings, especially the collection of those objects of special significance to individuals, groups, and states in human society. Throughout the world, treasures, relics, and books are kept or buried together in secret places. That's why we now know a lot about the unwritten histories through archaeological excavations, such as the oracles inscribed on bones or tortoise shells of Shang Dynasty in China, because those bones and shells were buried together intentionally after divinations by the Imperial Family.

Traditionally, antiquities were held in the private homes of aristocrats and the Imperial Family. Ordinary people could not view them and there was no thought of these objects being used for scholarly research or public education.

The notion of the modern museum was introduced to China by people from other countries. For instance, the earliest recognized museum, Xu Jia Hui (徐家汇) Museum, was a natural history museum which exhibited specimens of animals and plants. It was founded by a French Jesuit priest in 1868. The first modern museums in China were set up in the late 1870s. Important examples include the Imperial Tung Wen College (京师同文馆), established in 1876, and the Great Iron-House Museum (铁嵌玻璃房), established in 1877 by the Polytechnic Institution Shanghai (上海格致书院). In 1905, another major step in the development of museums in China was taken with establishment of the Nantong Museum (南通博物院), in Nantong, Jiangsu Province, by the famous industrialist and educator Zhangjian (张謇). The overthrow of the feudal imperial court during the Xinhai Revolution in 1911 facilitated the development of modern museums in China by removing social and cultural barriers to the public exhibition of treasured antiquities.

Chinese Museums of Note

The National Museum of China (NMC)

The National Museum of China is located on the east side of the Tian'anmen Square in Beijing. It was founded in 2003 after the merger of the former National Museum of Chinese History and the National Museum of the Chinese Revolution. NMC, an integrated national museum under the Ministry of Culture of the People's Republic of China, focuses on both history and art and is dedicated to its collection, exhibitions, research, archaeology, public education, and cultural communication.

The predecessor of the National Museum of Chinese History is the Preparatory Office of the National Museum of History, which was founded on July 9, 1912. Upon the founding of the People's Republic of China on October 1, 1949, the museum was renamed the Beijing Museum of History. In 1959, it was renamed the National Museum of Chinese History. The predecessor of the National Museum of the Chinese Revolution was the Preparatory Office of the National Museum of Revolution founded in March 1950 and renamed 10 years later. In August 1959, the construction of the new building on the east side of the Tian'anmen Square that housed both museums was completed. The building was regarded one of the "Ten Great Constructions" built to celebrate the tenth anniversary of the People's Republic of China. On October 1 of that same year, the two museums opened to the public.

The main aim of the National Museum of China is to be a leader within China and a first-class museum internationally. Its ethos is to put people first and for its development to be based on staff, collections, business, and academic research. This museum aims to protect Chinese cultural heritage, to display the time-honored history of China, to provide public education on history and culture, especially for young people, and to promote cultural exchange with other countries and regions. Through these efforts, the museum aims to create a classroom for lifelong learning and a palace for culture.

Palace Museum: Forbidden City in Beijing

The Palace Museum, China's largest museum, is situated in the center of Beijing. It was established on October 10, 1925. In Chinese, it is also known as the "Purple" Forbidden City, and in English as the Forbidden City. This museum covers 720,000 m^2 and was the imperial palace for a succession of 24 emperors and their dynasties during the Ming and Qing periods of Chinese history. The museum is China's largest and most complete architectural grouping of ancient halls. The construction of the Palace began in 1420, the eighteenth year of Yongle, so it is almost 600 years old.

More than 70 halls of various sizes, containing more than 9,000 rooms, comprise the Forbidden City. These halls are aligned along a north–south axis and extend out on either side in an east–west symmetry. The central axis not only passes through the Purple Forbidden City but extends south to Yongding Gate and north to the Bell and Drum Towers, for a length of some 8 km. This passage through the entire city of Beijing symbolizes the centrality of the imperial power: the imperial seat is at the very center of this line. The architecture is designed so that the buildings are lined up neatly and with imposing scale. In a concentrated form, this assemblage expresses China's artistic traditions in the setting of China's unique architectural style.

Shanghai Museum

The scope, depth, and quality of the Shanghai Museum's collections, and its striking architecture, make this museum one of the most famous, if not the most famous, in China. It covers an area of 38,000 m^2, with a scale that greatly surpasses its predecessor museum. The exterior of the museum is inspired by the shape of an ancient bronze *ding* (cooking vessel) of the Chen Dynasty, with its rather archaic flavor. The structure and materials of the entire building, however, are an accomplishment of the most modern technology.

The Shanghai Museum focuses mainly on ancient arts. At present, it is divided into 10 sections, which are ancient Chinese bronzes, sculpture, ceramics, jades, seals, calligraphy, coin and currency, paintings, Ming and Qing Dynasty furniture, and crafts of China's national minorities. In addition to these 10 permanent exhibitions, the museum holds small-scale exhibitions and hosts visiting exhibitions. The museum also lends to other museums, both within China and abroad.

Chinese Silk Museum

The Chinese Silk Museum is not only the first national silk museum but also the biggest silk museum in the world. It is located on the bank of West Lake, Hangzhou, Zhejiang Province. It was opened on February 26, 1992 "to spread the ancient silk culture and develop a new Silk Road," according to former Chairman Jiang Zemin. The main hall of the museum tells the origin and development of silk, the categories of silk, the Silk Road, and the role of silk in the ancient social life. The hall of dyeing and weaving and the hall of achievements in modern times exhibit separately the progress of ancient weaving machines and the great success in production, research, and foreign trade after the Liberation of the New China.

Chinese Tea Museum

The Chinese Tea Museum is a national theme museum, located in the Shuangfeng Village, southwest of Longjing Road, Hangzhou City, Zhejiang Province, the area where Longjing Tea originates. This museum opened in October 1990. The museum consists of independent but interrelated halls that cover the history of tea, collections relevant to tea service, and customs, and explains the tea culture from various angles.

Hu Tsing Yu House: Chinese Medicine Museum

Hu Tsing Yu House: Chinese Medicine Museum is China's first Chinese pharmacopoeia museum.

In 1874, a successful businessman named Hu Xueyan invested large sums in a handsome building of southern Chinese architectural style, which was the location of this museum. The exhibition halls display a wide variety of ancient implements and artifacts used in the conduct of the herbal medicine business. Hu Tsing Yu House is located in Hangzhou and enjoys the reputation of being a "magical science hall, brilliant medicine culture."

Cooking Culture Museum in Sichuan Cooking College

The Cooking Culture Museum is affiliated to Sichuan Cooking College. It focuses on the history, customs, and art of cooking and on relevant research, such as the relations between cooking and painting and calligraphy, cooking and celebrities, cooking and health.

Museum of the Terra-cotta Warriors and Horses of Qin ShiHuang

The Museum of the Terra-cotta Warriors and Horses of Qin ShiHuang was opened in 1979 to show the "Eighth Wonder of the World" in full scale. The museum was constructed on the site of the excavations. The main exhibits are three exposed pits with clay warriors and horses and more than 10,000 bronze weapons. In a sense, this museum is a treasure house of Qin's military affairs, science and technology, art, and culture. It is listed as a UNESCO World Heritage Site.

Zhoukoudian Site Museum

Zhoukoudian Site Museum is situated some 50 km to the southwest of the urban district of Beijing, where the world-famous Peking Man lived more than half million years ago. In 1987, UNESCO listed this site on the World Heritage List. More than 20 significant archaeological sites have been found at Zhoukoudian, including the Peking Man Cave, and the Upper Cave and New Cave. The discoveries of human and other animal fossils, human-made stone tools, and the evidence of fire use astonished the world when the discoveries were made in the 1920s. The Peking Man Site is not only a treasure house of human fossils but also the research base for paleoanthropology, prehistoric archaeology, paleontology, stratigraphy, chronology, and petrology.

Tonglvshan Ancient Copper Mine Museum

The Tonglvshan Ancient Copper Mine Museum was the first museum in China to focus on the history of ancient mining technology. The museum includes the copper mine's vertical shaft, heading, blind well, and inclined shaft. This ancient copper mining spot is thought to be the oldest in history. It is the largest in scale and the best-preserved mining museum in China.

Beijing Opera Museum

The Beijing Opera Museum is the 100th museum in Beijing. It is located in the Huguang Guild Hall, Xuanwu District, Beijing City, and has been open since 1997. The main hall was built in 1807 and includes the Grant Theatrical Stage, Ancestral Hall, and Wenchang Pavillion. During the period 1920 to 1940s, some of the most famous Peking Opera masters performed here, including Tan Xinpei, Yu Shuyan, and Mei Lanfang, making this one of the most attractive showplaces of that time. In 1912, Sun Yat-sen, the great revolutionary pioneer, visited the Huguang Guild Hall five times and used this location to host the founding conference of the Kuomintang. The masters from Beijing Peking Opera Theater perform operas here every night.

It is important to recognize that the Peking/Beijing opera is a member of a wider Chinese opera family. Many local opera museums have been set up all over the country, such as China's Kunqu Opera Museum in Suzhou, Tianjin Drama Museum in Tianjin, Cantonese Opera Museum in Guangdong, and the Shadow Puppet Museum in Xi'an.

Future Directions

Though China has a long history and abundant cultural heritage, it is a relative latecomer to museum ventures. In recent decades, the sector has undergone rapid development as social reform and opening up ushered in a wave of museum construction throughout the country. At present, about 80 large- and medium-sized museums are newly built, renovated, or expanded per year throughout China. So far, there are more than 2,500 museums in the country, 2,100 of which are state-run, with the other 400 being privately

owned. These museums specialize in history, politics, economics, culture, education, nature, science, astronomy, geography, ecology, and many other categories. Together, they house over 20 million artifacts. Every year, around 10 thousand exhibitions are presented to the public and these exhibitions draw more than 150 million visitors. As a result, a network of museums in cities has been formed; moreover, it is gradually expanding into rural areas. The future of China's museum undertakings has never been more promising.

China: New Approaches to Heritage Administration

Luca Zan
Department of Management, University of Bologna, Bologna, Italy

Introduction

Cultural Heritage and Heritage Administration

Why should one give attention to administration in the field of heritage, with so many fascinating aspects of material culture and archaeological finds? The problem is that heritage works and professions do not happen in a vacuum but rather within organizations, and most of the time, they take place within the public sector (the USA appears to be the exception more than the rule). If one wants to compare the changes that occurred in the last few years in, say, Machu Picchu, Pompeii, and the Qin Mausoleum, for sure a good part of these changes are explained by the evolution of professional discourse at the global level, including the increasing role played by international agencies (UNESCO, ICOMOS, ICCROM, etc.). Nonetheless, a good part of the differences is likely to be explained by internal dynamics of public sector in Peru, Italy, and China.

Key Issues/Current Debates/Future Directions/Examples

China: One of the Most Decentralized Countries

China has experienced an exceptional process of transformation in the last 30 years. From the initial situation of totally planned economy–with economic failures experienced over time, from the Great Leap Forward to the Cultural Revolution – since 1978, the "gradual revolution" (Wang 1994) began with the open door policy in both political and economic terms, which will transform China in the second world economy, with growth rates rarely seen before and elsewhere.

This also had an enormous impact in the transformation of the public sector (Zan and Xue 2011). A dramatic decentralization process took place, transforming China in one of the most decentralized countries in the world, a sort of "de facto federal state," as it has been observed (OECD 2005). Central organism has been relocated from the center to the province level or lower, public expenditures has been moved from the central government to the local level, with huge transfer of resources from the center to the periphery (Straussman and Zhang 2001).

Decentralization in Heritage Management

This general trend has serious impacts on heritage as well. About 90% of expenditures for the

cultural sector are decentralized, not even at the province level but rather taking place at the municipal and town level (OECD 2005). In terms of employees, out of the 77,000 people working in the sector, only few hundreds work in the central offices in Beijing.

Decentralization emerges also in terms of institutional settings within public administration. At the local level (prefecture, municipality, town), there is often a Cultural Relics Bureau which reports directly to the local level (usually to the Cultural department which reports to the mayor), with a mere professional relationships with higher levels of the same functional department. For instance, the CRB of Luoyang reports directly to the municipality, while the relationship with higher level of the professional body – the CRB at the Province level and the SACH (State Administration for Cultural Heritage) – is involved only in case of special projects, extraordinary events, or within a mere supervisory roles.

Such an institutional design is largely responsible of heritage destruction related to building and infrastructure constructions in the booming economy. Suppose the local administration is sensitive to economic development initiatives that have negative impacts on heritage preservation: in this case the professionals in charge of heritage protection have very little possibility to resist such project. They can try to stop it, simply on the basis of discussion and persuasion. In the end, the decision power is in the hand of the mayor, as well as their career and work assessment. The same situation would be different in Italy: the Superintendents – representatives of the Ministry of Culture at the local level – could easily express their negative opinion to the Ministry, in ways that are less subject to local dynamic and the pressure of vested interests at the local level. Though the term "centralization" tends to be seen as outdated, one of the serious problems in China preservation of heritage is indeed the excess of decentralization.

Economic Booming and Salvage Excavation

The general context of transformation of the country has other important impacts on approaches to heritage management in China. The extraordinary rates of economic growth and the associated rate of urbanization imply unprecedented levels of building and construction activities all over the country. And, consequently, there are extraordinary levels of new archaeological finds. The heritage chain – the chain of activities from excavation to conservation, research, and museum activities (Zan and Bonini-Baraldi 2012) – compared to other countries is here concentrated on early steps, on excavation, and on new finds, which have tended to completely revisit the taken-for-granted view of Chinese history, with very interesting controversies between archaeology and text historiography (von Falkenhausen 1993; Bagley 1999).

This huge archaeological activity however is once again related to administrative issues, with the explosion of salvage archaeology activities, which are responsible of most of the finds in recent years. According to the 2002 law on heritage protection (Law of the People's Republic of China on Protection of Cultural Relics, No.76, October 28, 2002: http://www.gov.cn/english/laws/2005-10/09/content_75322.htm, art. 30–32), before any construction can start, a preliminary archaeological inspection has to be run by the local administration (by the excavation team of the CRB at the local level). In case some sign emerges of archaeological finds, more extensive archaeological excavation is then run, funded – and this is the relevant peculiarity – by the construction company (see Article 31: "The expenses needed for the archaeological investigations, prospecting and excavations which have to be carried out because of capital construction or construction for productive purposes shall be included in the project budget of the construction entity"). Should the finds present high value, the building activity would be definitively halted.

Such an administrative mechanism could be seen as a very positive solution for China archaeology: the "business model" is that building and development activities "pay" for archaeological excavations (which mean huge amounts of money in a booming economy). Unfortunately, there are several shortcomings in such a situation (Guo et al. 2008): in the lack of clear definitions of

principal and related activities, the archaeological teams at the local levels have strong incentive mechanism to simply "dig": no budgets are devoted to research or to conservation of the finds. Indeed the archaeological teams in archaeologically intense areas – such as Luoyang, for instance – are unusually rich departments. The situation is worsened by institutional fragmentation, which does not address the collaboration between different entities: for instance, in Luoyang there are two archaeological teams of the local CRB doing almost only salvage excavation, with little, if any, coordination with four archaeological teams of the Institute of Archaeology of the China Academy of Social Science with excavation stations in the area, including Erlitou, a crucial excavation for the debate on early dynasties. Even when norms are defined by laws, not always are they followed. For instance, extensive reports on excavation should be presented within 3 years; finds should be transferred to the local museum's depot after this period. Actually, the lack of excavation reports is a serious problem undermining the possibility of knowledge diffusion; excavation teams sometimes are accused of not transferring the finds to museums.

National Identity Building and Museum Development: Administrative Issues

The general administrative transformation of the country has also direct implications for the ways in which museums are run, both in terms of design and development. From a formal point of view, museums (the same applies for archaeological sites) are defined as *shiye danwei*, as public sector units (PSUs), as this term is usually translated in English (Pilichowski 2005). They are, in a sense, "entities" established as operative arms of the respective governmental level, with their own collections and often building, financial statement, personnel, in a word their administrative identity.

There are very few national museums (directly reporting to the SACH); some important ones are provincial museums (they refer to the Cultural Relics Bureau at the province level); most are district, municipal, or town museum (i.e., reporting to the CRB of these levels). In any case, the process of decentralization is to be intended as devolution more than anything similar to the Anglo-American mechanism of the arm's length principle. The transfer of power is from the central government to the provincial level, and for the most part at lower levels, more than from each governmental level to autonomous operating entities. In other words, at each governmental level, there is a strict control over museums reporting to this level, and there is not an issue of autonomy of the entity in itself.

An important distinction made by the Chinese regulation was between museums that were totally funded, partially funded, and financially self-funded, in relation to different kinds of economy of each entity. This was likely to pose different issues in the day-to-day running of museums and in development terms. Self-funded museums tended to be very powerful centers: with interesting collections, good appeal to visitors and good location, with Western prices and Eastern costs, they could be profit-seeking entities as it is rarely in the West. They were often able to contribute to determining future developments, always in strict accordance with the governmental level to which they refer to. On the contrary, for museums that were not totally self-funded, resources for functioning were provided at the local level; developmental ones, link to special projects, were provided by the SACH in accordance with the CRB at the provincial level (and may be involving CRB of lower levels as well).

In any case, for day-to-day life, museums have to use administrative rules and the table of accounts that are common to the other (almost one million) *shiye danwei* in the country. This is raising serious problems for activities that are so crucial for museums but for whom it is even impossible to find an entry in the national table of accounts (e.g., conservation, maintenance). Indeed maintenance and conservation are some of the most problematic issues for Chinese museums (Li 2005), as it has been explicitly acknowledged even in formal documents (see, for instance, the 11th Five-Year Plan).

In terms of development, there is a strong policy at the central level to build new archaeological sites (about a hundred, in the 11th Five-Year Plan) and museums. According to the new 12th Five-Year Plan for Cultural Heritage, there should be one museum in each of the 333 prefectural levels, with a goal of passing from 3,020 to 3,500 museums in the five years). This is partly explained by the increase of tourism in the recent years (especially domestic), but it is also linked to a more general politics of national identity building, if not nationalism (a well-known issue in the international debate: see Vickers 2007). For such a developmental program, the center had already defined a sort of development plan during the previous Five-Year Plan horizon, offering a huge amount of money to gain the consensus at lower governmental levels' plans (for instance, for the archaeological parks, the initial assumptions – later further expanded – were about 36 billion RMB for 2006–2010, where 53% was provided by central government). However, running costs were not identified nor budgeted and much less so funded, which is likely to pose serious problems in the future, once the investment phase for new museums and parks will be over and the issue of "running costs" will emerge. Maybe some of the new entities will be self-funding; for the rest, serious problems of sustainability will take place, also in connection to the decision – taken by center – to generalize the free entrance to museums already started with a few exceptions since 2008. As always, the issue of sustainability appears as a problem at later stages if it is not being addressed as an issue in earlier stages. This happens very often in the arts and heritage sector: what is peculiar of the Chinese situation is however the scale of the phenomenon.

Between Centralization and Decentralization

Indeed administration matters. Both longer term administrative traditions and recent transformations have an impact on the ways in which heritage is managed in China, from excavation, to research, to museum opening. Curiously enough– and quite counterintuitively if one does not know the Chinese administration – the excess of decentralization explains to some extent the destruction of heritage often referred to (professionals in charge of protection are "hostages" to the local administration; incentive mechanisms toward digging activities; institutional fragmentation and jealously; lack of respect of norms).

However, there are also positive aspects related to the explosion of salvage archaeology and its intrinsic anarchist nature in pluralizing the past (the impossibility to plan and direct it in systematic ways). Similarly, potential influences refer to the following steps of the heritage chain (research, conservation), and particularly museum development, as narratives about the material culture and archaeological finds are unlikely to resist similar debates in the middle run. From this point of view, salvage excavation appears as a strong antidote to ideological uses of heritage from any central (and centralist) views. The variety of empirical evidence that characterizes China archaeology in the last few decades, largely based on salvage archaeology, has questioned to a serious extent traditional views of linear developments of China over millennia, with the emergence of a very interesting – and unusual elsewhere – conflict between archaeology and historiography in China, between empirical evidence and text-driven explanations. Moreover, the controversy about the very existence of the first dynasty is perhaps the best example of the dialectic between different forms of archaeology, where research archaeology was explicitly aimed at giving evidence to the 5,000 years of Chinese history within a nationalist frame (the Xia-Shang-Zhou Chronology Project. For a reconstruction, see Lee 2002: 16–17). These aspects have been extensively addressed by archaeologists in their substantive elements, sometime Western archaeologists (von Falkenhausen 1993; Bagley 1999) and sometimes Chinese archaeologists outside China (Lee 2002; Li and Xu 2007). Here the administrative foundations of this revolution have been addressed.

More difficult is to foresee how the dialectic between centralization and decentralization will have an impact in terms of museums and archaeological parks. On the one hand, a tension

between different policy preferences can be found, with the central government pushing a policy of national identity building and free entrance, while often the periphery would be more seduced by profit-maximizing museum projects, related to tourism development (the over-commoditization of Lijiang is the best example in this sense: see, for instance, McKhann 2001, 2010). Heritage professionals and their values (archaeologists, museologists, and historians) sometimes find themselves in conflict with both the extremes of this kind of policy tension. On the other hand, it is the administrative mechanism that makes the overall result of similar tensions more uncertain than usual: the separation between investment and running conditions – a recurrent problem in the heritage field – is here associated with a separation between governmental levels in funding extraordinary projects and their running costs at a later stage.

Chinese Archaeology in the Twenty-First Century

Liangren Zhang
School of History, Nanjing University, Nanjing, Jiangsu, China

Chinese archaeology, after the devastating Cultural Revolution (1966–1976), finally embarked on a normal track of development. In the era of the

"Reform and Open Door (改革开放)," the Marxist paradigm faded away from the academic sphere, whereas the regionalist paradigm arose to become the new beacon for Chinese archaeology (von Falkenhausen 1996). This paradigm, juxtaposed with the rejuvenated historiographical and antiquarianist orientations, however, continued to hamper Chinese archaeology from playing out its full potential (Falkenhausen 1993: 847; 2015: 148). Since the late 1990s, while these forces remain omnipotent, a number of new developments have gradually mitigated their power. As a result of the rocket-like rise of economy, the entire country plunged into an unprecedented period of feverish modernization of infrastructure and urbanization. The grand construction projects and the rapidly growing state funding for research projects have injected vitality, perhaps too much and too fast, into the long-sluggish discipline. In the meantime, the influx of international expeditions and Western theories gradually transformed Chinese archaeology and triggered a thorough overhaul of the outdated fieldwork manual in 2009. The new manual, which was rigorously implemented by the State Administration of Cultural Heritage (hereafter SACH) to the entire country, has revolutionized the paradigm, methodology, and technological equipment of Chinese archaeology, which in turn has empowered it to reorient their research agenda, dispatch expeditions to foreign countries, and develop underwater archaeology.

Mega Infrastructure Modernization Projects

The Three Gorges Dam was designated to build up a dam in the middle of the Yangtze River; planned ever since the 1910s, it was put into execution in 1994. Within the affected area of 1074 km^2, archaeological work had been sporadically done since the 1950s, and a number of important sites, including Longgupo in Wushan County, where an ape of 2 million years ago was found, had been uncovered; after the start of the project, an extensive archaeological survey was carried out which recorded 1074 sites, including 723 underground ones. These sites, however, had to be taken care of within a mere 15 years, i.e., 1994–2009; thus, although over 30 universities and archaeological institutes from all over the country poured their manpower into this area, only a small fraction of them was subject to proper rescue excavation. The most extraordinary discovery was the salt production site at Zhongba in Zhong county, where 6 years of excavation exposed nearly 100 tombs, 300 house foundations, and 600 trash pits within an area of 6600 m^2 (Liu et al. 2003: 65). The cultural deposits, altogether 12.5 m thick, comprised strata of the Neolithic Age through the Qing dynasty (Liu et al. 2003: 65). The discovery of a stratum of the Daxi culture at Liujiaba in Wushan county advanced the record of the earliest human activity in this area to as early as 5000BC. These sites, together with the historic site of Baidicheng in Fengjie county, whether or not completely excavated, were all submerged under water after 2009 (Liu et al. 2003: 64).

This ushered in a succession of grand projects. The South-North Canals Project, which was meant to deliver water from the Yangtze River to alleviate the draught that has long stricken northern China, consists of three lines, among which the Eastern and Middle Lines have been implemented. The Eastern Line, which links the Lower Yangtze River to the city of Tianjin, passes through Jiangsu, Shandong, and Hebei Provinces. Utilizing the historical Grand Canal, rivers, and lakes along the way as well as building dozens of pumping stations, this line was started in 2002 and completed in 2014. Over 50 institutions from all over the country participated in the survey and excavation in the affected area within Jiangsu province alone, discovering a number of important sites, including the Han dynasty city of Liangwangcheng, the Han dynasty lineage cemetery of Shantou, and a cluster of tombs of the Yuan, Ming, and Qing dynasties pertaining to the active operation of the Grand Canal (Lü 2013). The Middle Line is used to draw water from the Danjiangkou Reservoir in Hubei province and transmit it through newly built canals in Henan and Hebei provinces and finally reach the cities of Tianjin and Beijing. Within the affected territory, over 600 sites had to be excavated within 9 years (2004–2013). About 24 institutions were

involved in the excavation campaign, and by 2009 a half of them were excavated. Among them, the Yangshao culture settlement of Longshangang in Xichuan county, the late Shang settlement of Guandimiao in Yingyang city, the Eastern Zhou Chu cemetery of Xujialing in Xichuan county, and the royal cemetery of the Northern Dynasties in Yecheng are all important sites (Zhang and Liang 2010).

Preservation of Important Sites

All of the above projects, plus the West-East Gas Pipelines, the high-speed railway and freeway networks, as well as the rapid urbanization all over the country, put ancient urban centers, settlements, and cemeteries, especially those located within or adjacent to modern cities, at risk of destruction. Although the Chinese Cultural Relic Protection Law (中华人民共和国文物保护法) was issued in 1982 and amended several times thereafter (http://www.npc.gov.cn/npc/xinwen/2017-11/28/content_2032718.htm), it is up to the discretion of the all-powerful governments of the Central and Provincial levels whether to respect it or not. The state and provincial administrations of cultural heritage could not challenge but usually bend to the desire of, or sometimes collaborate with, the governments. Many of the affected sites had been designated as National Cultural Heritage, but they were either perceived as peripheral matters or as annoying obstacles to economic development, or overexploited as tourist attractions (Lu 2005: 121).

Alarmed by the escalating destruction to the archaeological sites, particularly those of national significance, such as the late Shang capital at Anyang, and the Sui and Tang dynasties capital at Xi'an, SACH figured out two strategies. One is to increase the number of applications for adding sites to the World Cultural Heritage List. China joined the *Convention Concerning the Protection of the World Cultural and Natural Heritage* in 1985, and by 2002, it had put 23 major sites, i.e. the Paleolithic site of Zhoukoudian, the Dunhuang Grottoes, the Terracotta Army, the Longmen Grottoes, and the Yun'gang Grottoes, on the list. This helped to implement protection programs, to change the attitude of the local governments and populations, and to bring tourist revenues. Since 2001, SACH became more active in organizing these applications, even setting up a department specifically handling them, and overseeing the protection of the World Heritage sites (Li 2004). To date, 17 more archaeological sites, including the late Shang capital at Anyang, the city and mausoleums of the Koguryo kingdom in Ji'an, the Silk Road, the Grand Canal, the Yuan dynasty city of Shangdu, and the Ming and Qing dynasties complexes of Tusi, have been named as World Heritage sites (available at http://whc.unesco.org/zh/list/).

The other strategy is to focus on the "Great Sites (大遗址)," that is, large and significant sites. Since 2002, SACH has integrated programs of investigation, protection, and display of these sites into the national Five-Year Plans of development, which the local governments have to execute faithfully. In the beginning, 50 sites were included in the Eleventh Five-Year Plan (2006–2010), then 100 in the Twelfth Five-Year Plan (2011–2015), and 150 in the Thirteenth Five-Year Plan (2016–2020). These programs entail the freezing of the territory of the site from any major developments, very much to the distress of the local governments, who lose valuable land for social and economic development. As a practical way of easing the tension between their interests and the programs, site parks were advanced as a solution for sites within or adjacent to modern cities. This solution turns a site into a recreation area or tourist attraction, and allows the local government to use the surrounding land for development. Such solution had been tried at the site of the Qujiang Pond (1996–2007), the imperial garden of the Tang dynasty capital of Chang'an. Once exalted as "the Qujiang model (曲江模式)," the project has invited much critique, because it destroyed any cultural deposits in the surrounding area. Nevertheless, the same solution is now being implemented at other "Great Sites" (Wang 2008).

Archaeologists have participated in the planning and execution of both the World Heritage application and the "Great Sites" protection projects; for both objectives, they have carried out a

great deal of fieldwork for the sake of understanding the dimensions, cultural value, and preservation strategy of the target sites. Among them, Liangzhu figures very prominently. In the 1980s, the site was discovered to have one large walled settlement and three aristocratic cemeteries, whose tombs were furnished lavishly with jade objects. But as it is located near the economically vibrant city of Hangzhou, it became increasingly entangled with the expansion of the city. In 2001, the provincial government of Zhejiang set up a protection zone for the Liangzhu site, in which a park was planned and urban development was barred, whereas the surrounding zone was urbanized. Since 2006, Liangzhu has been exalted as a model site, included in the protection program of SACH and placed on the list of application for World Cultural Heritage. Thanks to both programs, large-scale excavation was resumed, leading to the discovery of the water-diverting canals outside the complex and rice paddies near the large walled settlement (Renfrew and Liu 2018).

The Origin of Chinese Civilizations Project

In 1996, a grand research project, "the Xia-Shang-Zhou Chronology (夏商周断代工程)," was initiated by Song Jian (宋健), then head of the National Science Committee (now Ministry of Science and Technology), to refine the chronologies of the Xia, Shang, and Zhou dynasties, the earliest dynasties recorded in Chinese historical accounts. The chronology of the three dynasties had in fact been tackled by generations of scholars, both Chinese and international, in various fields. The existence of the Xia dynasty has been and is still doubted by some scholars; however, as Song and other top leaders of China were upset by the fact that the "Chinese civilization" is not as old as those of the Near East and Egypt, a project should be undertaken. Specialists from various research institutions were mobilized to work out a finer chronology, a modest yet difficult objective. Nine teams were organized to deal with nine subjects: historians (headed by Li Xueqin 李学勤) were to collect records of datable events in received texts; archaeologists (headed by Li Boqian李伯谦) were to excavate at key sites such as Erlitou, Yanshi Shangcheng, Anyang, and Fengxi, to find diagnostic cultural strata for dating Xia, Early Shang, and Late Shang; astronomers (headed by Zhang Peiyu 张培瑜) were to search oracle bone and bronze inscriptions for astronomical events that anchor the date of King Wu's conquest of the Shang dynasty and the reign dates of all the kings of the Western Zhou; dating scientists (headed by Qiu Shihua 仇士华) were to provide a fine-grained chronological series of radiocarbon dates. Marred by internal disagreement, the project was concluded in 2000 without producing the wished-for results (Xia-Shang-Zhou Duandai Gongcheng Zhuanjiazu 2000).

The project nevertheless provided an ideal precedent for other large multiyear projects to come. In 2001, the grand project, "The Origin of Chinese Civilizations (中华文明探源工程)," was launched to further fulfill the aspiration of Song Jian. It was tailored to prove the long-held claim of the existence of "Five Thousand Years of Chinese Civilizations," which would make the Chinese civilizations equal with Near Eastern and Egyptian Civilizations. Some scholars, international and Chinese, are doubtful of this claim, which would require the Chinese civilization to have risen before 3000BC, in archaeological terms, within the Neolithic Age. The Ministry of Science and Technology was nevertheless fully supportive of the project. Under the leadership of two archaeologists Wang Wei (王巍) and Zhao Hui (赵辉), a multi-institutional and multidisciplinary team was organized in the same manner as for the Xia-Shang-Zhou Chronology Project.

After 2 years of preparatory work, the project was officially activated. During its first official stage (2004–2005), the project was set to focus on the region of the Central Plain and the period of 2500–1500BC, or the Longshan, Erlitou, and Early Shang periods, addressing five subjects: (1) a fine-grained radiocarbon chronology of the archaeological cultures in the region; (2) the natural environment; (3) settlement pattern and social structure; (4) economy and technology; and (5) the formation of Chinese civilization. When it came to the second stage (2006–2008), the same

set of questions was posted to address the period of 3500–2500 BC, or the late Yangshao and the early Longshan periods; it was also extended to include the important sites of Shimao in the Ordos Plateau, Taosi in the middle Yellow River, Shijiahe in the middle Yangtze River, Liangzhu in the Lower Yangtze River, and Niuheliang in the Liao River Valley. A third stage (2009–2015) was undertaken to wrap up the project (Wang and Zhao 2012), although no official reports have been published to date.

Based on the data it had acquired, the project proposed a new set of material indicators of civilization: the development of agriculture and craft production; the building of monumental settlements and public structures that demand a large great deal of labor investment; the building of palaces and temples that display royal power; the use of ritual objects that manifest sophisticated craftsmanship and high status. The Neolithic sites of Niuheliang in Liaoning province and Lingjiatan in Anhui province, dated to 3500 BC and featuring large tombs furnished lavishly with jade objects and grand ritual structures, thus arrive at the threshold of civilization; the sites of Liangzhu and Taosi, dated to 3000–2000 BC and featuring grand settlements, massive palaces, and large tombs, have passed the threshold toward state-level society and civilization. During the next period, the imposing palaces, ritual bronzes, and bronze and turquoise workshops lift the Erlitou culture to the stage of "royal state (王国)," a home-grown term that designates the Shang and Zhou dynasties. The project thus inferred that civilization emerged in the Neolithic Age in several of the outlying regions, but all these civilizations disappeared to give way to the single "royal state" in the Central Plain in the Bronze Age (1750–500 BC, Wang and Zhao 2012).

After the completion of the project, SACH funded another project "Discovering China (考古中国)." With an ambiguous yet trendy title, the project follows the spirit of the previous one to investigate the formation of civilizations in the Central Plain and the outlying regions, including the Ordos Plateau, the middle and the lower Yangtze River, highlighting the star sites of Shimao, Shijiahe, Liangzhu, and significant, newly discovered sites. Unlike the previous two, the project is directed by SACH and executed by provincial institutes of archaeology; without any temporal and spatial constraint, it is flexible enough to incorporate any new discoveries of any period which bear on the origin of Chinese civilization, the origin of human beings in China, and the formation of the multiethnic unity of China: that is, grand walled settlements, monumental structures, rich cemeteries, even the imperial mausoleum of the Liao dynasty. Designated as a priority project of SACH during the Thirteenth Five-Year Plan period, it is yet in progress; as such, only some discoveries have been reported (Li 2018).

International Fieldwork Projects in China

After the rise to power of the Chinese Party, political circumstances forced Chinese archaeologists to cut connections with the West in the 1950s, then with the Soviet Union in the 1960s, and thus with all the major archaeological communities of the world. By the late 1970s, only a few top Chinese scholars were sporadically in touch with foreign archaeologists. There were no foreign research projects in China, nor Chinese field projects in foreign countries, with but one exception. In the early 1960s, upon the request of North Korea, a joint Sino-Korean expedition was organized to investigate sites of the Neolithic and Bronze Ages, Koguryo, and Bohai periods in northeastern China. But the subsequent territorial conflict between the two countries caused the Chinese government to shut the door to international collaborative projects. It was only in the 1990s that China was reopened (Zhang 2019).

The first international collaborative project on Chinese soil was that of Harvard University, led by Kwang-chih Chang (1931–2001), who had strenuously sought for such a project since the late 1970s. In 1990, his project of searching for the proto-Shang capital in the Shangqiu City was finally landed on the ground (Zhang 2019). This project was followed by other ones from the USA, France, and Japan. These international

expeditions brought not only funds that China was badly lacking, but also new research agendas and methods. Among them, the teams of the Andover Foundation for Archaeological Research Foundation and Harvard University came to Jiangxi and Hunan Provinces to study the origin of rice agriculture (Zhang 2019). The teams of Yale University, Minnesota University, and University of Pittsburg introduced the approach of regional survey to the Liangcheng zhen site in Shandong Province, the Huan River valley in Henan Province, and the Chifeng region in Inner Mongolia (Zhang 2019). The team of the University of California, Los Angeles (UCLA), investigated the salt production site of Zhongba in the Three Gorges area before it was drowned. Among the French and Japanese teams, those from the National Scientific Research Center of France and the Buddhist University of Japan investigated a few ancient Buddhist monasteries deep in the Tarim Desert (Zhang 2019). Thanks to these field projects, the study of Chinese archaeology in the West and Japan has grown significantly (Zhang 2019).

New Archaeological Fieldwork Manual

The "Xia-Shang-Zhou Chronology" and the "Origin of Chinese Civilization" projects as well as the international field projects brought new theoretical paradigms and new research strategies to Chinese archaeology, which prompted a thorough overhaul of the outdated *Archaeological Fieldwork Manual*. First issued in 1984, the manual was modeled upon the regionalist paradigm. The typological method was introduced to China and adapted to Chinese data by Su Bingqi (苏秉琦, 1909–1997) (Hein 2016). In the frenzied development of the "Marxist Chinese archaeological system (马克思主义中国考古学体系)" in the 1950s, typology was attacked as "bourgeois." Su nevertheless kept pondering over the regional cultural distinction of the Yangshao (5000–2800 BC) and Longshan (2800–1800 BC) periods. After examining archaeological cultures in more regions in the 1970s, he began to develop the theory of "regional cultural genealogy and variation (区系类型)," which sought to establish the cultural sequences of individual regions. In a time when most archaeologists, Chinese and international, held on to the traditional outlook that the only civilized part of China was the Central Plain, the theory gave due respect to the multilineal development of regional cultures, and gave rise to the notion of "multiple origins of Chinese civilizations (满天星斗)" (Zhang 2013).

This theory, which constituted the backbone of what some call the "Chinese school" of archaeology, was the mother of the 1984 manual, a collective work compiled by Yin Weizhang (殷玮璋). The establishment of regional cultural sequences was thus taken to be the primary objective of Chinese archaeology. Since the 1990s, however, new theories and fieldwork methods streamed in from other countries, and the constraints of the 1984 manual appeared acute. Thus in 2005, SACH commissioned Peking University to conduct a major revision of the manual. From manuals of Britain and Japan, a whole set of survey, excavation, recording, storage, and conservation guidelines are borrowed (Zhang 2014). A broad spectrum of subjects of settlement pattern, subsistence economy, craft production, and social organization are adopted. A full-coverage survey is instituted to investigate the distribution of artifacts, the natural environment, and local resources of a site. During excavation, attention is given to the spatial organization and the formation process of the site. Sifting and flotation are implemented to collect animal bones and plant seeds for further archaeobotanical and zooarchaeological studies. An excavation project is no longer aimed at narrow subjects such as the definition, chronology, and ethnic association of a culture, but at wider range of subjects and multidisciplinary research. Much attention is paid to issues of conservation. Understanding that cultural artifacts are most vulnerable to damage at the moment when they are exposed to air, it stipulates that conservation personnel and apparatus be ready on site so that fragile artifacts can be taken care of instantly (Zhang 2014). Delicate artifacts are given instant consolidating treatment instead of being left to turn into powder; particularly small artifacts are transported in their original block of earth to

laboratories to be excavated there under minute documentation rather than being taken out quickly in the field (Zhang 2014).

Before implementing the manual on all field projects in the country, SACH commissioned several trial applications so as to demonstrate its advantages to the field archaeologists as well as to collect feedback for improvement. For instance, in 2011, a group of archaeologists of Shaanxi Province undertook a systematic survey of the walled settlement of Shimao. An old-fashioned survey and a test excavation had been conducted there in the past, but the site remained poorly understood. This time the team carried out a full-coverage survey of a 20-m-wide transect, recorded GPS data and architectural features, and gathered all pottery shards within the sampling zones. As a result, the knowledge of the settlement was augmented dramatically. The two circles of walls of the settlement were discovered and its dimension was accurately worked out as 425 ha (Zhao 2016).

Chinese Field Projects in Foreign Countries

The new manual, vigorously promulgated by the SACH through field training programs and inspection of on-going fieldwork, leads not only to the improvement of fieldwork and research standards, but also to the upgrade of research facilities, including fieldwork equipment, conservation and research laboratories, as well as university curriculum to catch up with the progress in the field. The annual "Top Ten National Discoveries" Award, started by China's Cultural Relics Weekly (中国文物报) in 1990, and the "Six National Great Discoveries" Award, started by the Institute of Archaeology of Chinese Academy of Social Sciences (中国社会科学院考古研究所) in 2010, compel archaeologists to refine their fieldwork and research. Among all the archaeological discoveries of the year all over the country, ten or six are selected for the awards. As time goes on, the awards ascribe increasing value to the fieldwork and research methodology of archaeologists as well as the scholarly significance of the discoveries. Highly visible in national media such as CCTV and Xinhua News, the award ceremonies of the two awards have become occasions of pompous gala like the "Oscar Award." Archaeological institutions and local governments scramble to use state-of-the-art technologies and conduct multidisciplinary research, and conjure up nationalism and the Party ideology of multi-ethnic unity of Chinese civilization, to win them. As a result, they have charged archaeological institutions with plentiful energy to update their fieldwork and research capacities, which quickly reach the threshold of excess. It is now not only possible but also necessary for them to export these capacities to foreign countries.

Chinese institutions began to send expedition to foreign land in 1998, when the Ministry of Commerce, upon the request of UNESCO, funded the Chinese Institute of Cultural Heritage to conserve the ancient city of Angkor Wat in Cambodia, which included archaeological investigation. In 2005, it funded another project in Mongolia, organized by the Inner Mongolian Institute of Cultural Relics and Archaeology, to investigate Xiongnu, Uighur, and Turkic cemeteries. After President Xi Jinping announced the "One-Belt-One-Road" Initiative in 2013, the number of teams dispatched to foreign countries has increased significantly (Zhang 2019). Most institutions, however, have to secure their own sources of funding, which are much less bountiful and sustainable; SACH, quite surprisingly, cannot help much. The first teams sent by the Heilongjiang and Jilin Province Institutes of Cultural Relics and Archaeology, as well as Jilin University, to the Far East of Russia in the early 2000s turned out to be ephemeral (Zhang 2019). The project of Northwest University in Uzbekistan and Tajikistan was in a better situation, because it received a sizeable fund from the provincial government of Shaanxi (Zhang 2019).

In a time of economic recession in many countries throughout the world, the Chinese teams provide not only much-needed funding for archaeological research, but also bring refined expertise and technical equipment to the target countries (Wang 2017). After several decades of

fieldwork, Chinese archaeologists have developed an extraordinary expertise in field survey and excavation; in most regions of China, houses, ash pits, and tombs are built of earth materials, without using stone or mud-brick, and in most cases, they are hardly distinct. But Chinese archaeologists have mastered the skills and tools needed to discern them. The expedition of the Institute of Archaeology of the Chinese Academy of Social Sciences, to Uzbekistan, which was started in 2012, brought both of them to the site of Ming Tepa. The site was known to have one round of wall (500 × 800 m) only, but after systematic application of the so-called Luoyang drill, a handy and efficient tool for survey work originally developed by grave robbers, it was found to have an outer wall, which effectively expanded its size to 2100 × 1300 m. It was also found, again with the tool, to possess two roads, and a cemetery outside the eastern wall. The Chinese drill was also brought by a team of Nanjing University to Iran to define the boundary of Tepe Naderi in Northern Khorasan Province. The area around the Tepe has been buried under multiple layers of silt and washout from the Tepe; the use of the drill in 2016 enabled the Sino-Iranian Joint Expedition to define the original ground and boundary of the Tepe (Zhang 2019).

By the end of 2017, Chinese institutions have sent 22 expeditions to 13 countries over the globe. Most of them work in countries along the "Belt and Road," including Kazakhstan, Bangladesh, as far as Kenya. The rapid development of international projects in the last 18 years, however, has not been well prepared for. Most of the Chinese directors do not master the language and archaeology of the target countries. What's worse, no archaeological program at Chinese universities offers any training in the archaeology of any foreign country. Because of the lack of trained personnel, the excavation materials are published only in Chinese and the language of the target countries, thus inaccessible to most scholars of the international archaeological communities. To make the field projects in the foreign countries sustainable, such archaeological programs are urgently needed (Zhang 2019).

Underwater Archaeology

Owing to the growing economy of China, underwater archaeology has been rapidly developed as well. Underwater cultural heritage, i.e., shipwrecks, caught the attention of Chinese archaeologists in 1987, when an Australian company excavated 239,000 items of Chinese porcelains from a wrecked ship in the South China Sea and sold them on the international antiquities market. The Center for Underwater Archaeology was thus founded at the National History Museum; in the 1990s, young personnel were sent to Japan, USA, and the Netherlands, to learn underwater excavation techniques. In the meantime, the center began to survey Chinese waters, and discovered a number of shipwrecks in subsequent decades (Wu 2007). A prominent discovery was made of an ancient commercial boat, "Nanhai I." Loaded with celadon wares of the Southern Song dynasty, the boat was entirely salvaged and delivered to a museum specifically built for it in 2007 (Zhang 2019). Since 2014, the boat "China Archaeology 01," especially designed for underwater archaeology, and three research bases have been put into use, which augment the capacities of the center (Zhang 2019).

Along with the growing number of field projects in foreign countries, the center, renamed the National Center for the Protection of Underwater Cultural Heritage and placed under SACH in 2009, sent a team to Kenya. The well-known Chinese fleet dispatched by the early Ming Court in 1405–1433 reportedly reached East Africa, which seems to be well attested by abundant Ming dynasty ceramics found there (Zhang 2019). A report of local descendants of Chinese sailors, who survived the capsizing of a ship, by *The New York Times*, caught the attention of the Chinese government. Suspecting that Zheng He (郑和), the commander of the fleet, actually landed there, SACH sent specialists to investigate the site in 2005, and after 5 years of pilot survey, dispatched underwater archaeologists to the seabed of the Lamu Archipelago and Marindi Bay (Zheng 2019). Although it failed to find substantial evidence for the landing of Zheng He, the

team made a number of important discoveries, including a shipwreck dating to the sixteenth/seventeenth centuries and coming from Portugal found in Ngomeni Ras, which is filled with elephant tusks, copper ingots, mercury, copper molds, and glazed pottery (Zhang 2019).

Conclusion

The development of Chinese archaeology in the twenty-first century, as the above review suggests, is phenomenal. Due to the limitation of space, this brief glosses over a few concurrent events, i.e., the rampant occurrence of tomb-robbing and the mushrooming of new museums, but it presents the major ones. Following the economic boom of China, the large-scale infrastructure projects, such as the Three Gorges Dam, the South-North Canals, plus the West-East Gas Pipelines, the high-speed railway and freeway networks, and rampant urbanization have brought long-dormant archaeological institutions a flood of rescue excavation and funding. On top of that, the state-funded preservation projects of the "Great Sites" and the research projects such as "The Origin of Chinese Civilizations" and "Discovering China" have further enhanced their vitality. On the one hand, the amount of fieldwork and data may have been too much and too fast for archaeological institutions to absorb. On the other hand, the lavish amount of funding and influx of new theories and methods have significantly boosted their capabilities, the momentum of which SACH quickly picked up and disseminated to the entire country through the revised *Archaeological Fieldwork Manual*. The improved capacities have even enabled Chinese institutions to send expeditions to foreign countries and develop underwater archaeology. As a result, Chinese archaeologists have been able not only to free themselves from the prolonged yokes of the regionalist paradigm, the historiographic and antiquarianist orientations, but also to interact more actively with the international archaeological communities, by engaging themselves in more intense exchange of scholarship and fieldwork in foreign countries.

Chinese Association for Quaternary Research (CHIQUA)

Ying Guan
Department of Paleoenvironmental study, Institute of Vertebrate Palaeontology and Palaeoanthropology, Beijing, China

Basic Information

The Chinese Association for Quaternary Research (CHIQUA) was established in February 1957 in Beijing, China. Geologist Siguang Li was elected as the first president and Chung-Chien Young and Defeng Hou the first deputy presidents (Liu 1957). From then on, CHIQUA has been dedicated to the organization and coordination of domestic and international academic communication and making great contributions to Chinese Quaternary Science. The Secretariat office is in Beijing and affiliated to the Institute of Geology and Geophysics in the Chinese Academy of Sciences.

Address

19 Beitucheng West Street, Beijing, 100029, China.
The official website address: http://www.chiqua.org.cn/
Tel: 86-10-82998551
Fax: 86-10-62052184
E-mail: dsjx@mail.igcas.ac.cn

Major Impact

Quaternary is the latest period in the geological history, which refers to the origin and evolution of human beings and dramatic climatic fluctuation. The impact of human activities to natural environment has been hotly debated for a long time by researchers from different working areas, and vice versa; the influence of geological and geographical contexts on human beings is also pursued in broad extent. With these research issues, quaternary research borrows modern technologies, with the help of the geological record, and aims at the reconstruction of geological history of our earth during past millions of years, pursues the motivation and mechanism of all the changes and the fluctuations, interprets the correlation of human beings and natural environment, and estimates the future changes of earth and the associated regulations.

With such goals, CHIQUA refers to multiple subjects including earth science, biological science, physical science, and even social sciences. One of the main responsibilities of CHIQUA is to integrate these disciplines and organize the researchers from all these fields for addressing the related issues. In this case, until now, 15 professional committees have been set up in CHIQUA, which cover all the research fields of quaternary science. These subjects are stratigraphy, high resolution, loess, paleoanthropology and paleolithic archaeology, coastal zone and ocean science, environmental archaeology, environmental change, education and science popularization, chronology, Holocene science, tropic and subtropic research, coral reef science, neotectonic movement, and applied quaternary science.

In 1982, the International Union for Quaternary Research (INQUA) admitted China to its national membership. From then on, CHIQUA involved the associated affairs on behalf of China and has made great contributions to international earth science.

Chinese Association for Quaternary Research (CHIQUA), Table 1 Annual meetings of the Chinese Association for Quaternary Research

Annual meeting	City	Time	Year
1st annual meeting	Beijing	February 11–15	1957
2nd annual meeting	Xi'an, Shaanxi	October 30–November 3	1964
3rd annual meeting	Beijing	June 10–16	1979
4th annual meeting	Beijing	April 10–15	1987
5th annual meeting	Beijing	August 2–9	1991
6th annual meeting	Guangzhou, Guangdong	November 15–22	1993
7th annual meeting	Beijing	November 2–6	1997
8th annual meeting	Dujiangyan, Sichuan	August 20–24	2002
9th annual meeting	Nanjing, Jiangsu	October 9–11	2006
10th annual meeting	Lanzhou, Gansu	August 18–20	2010
11th annual meeting	Guiyang, Guizhou	August 15–18	2014

For promoting the research of quaternary science, especially the Cenozoic paleontology and Qinghai-Tibetan Plateau environment and geology, and encouraging young scholars in these fields, CHIQUA set up the Liu Tungsheng Earth Science Foundation and established the awards of the Liu Tungsheng Prize for Young Earth Scientists and the Liu Tungsheng Scholarship for Earth Sciences. Every two years, not more than three awardees are selected.

Until now, 11annual meetings have been held in different cities of China (Xia et al. 2010), during which researchers have presented their latest achievements and progress. The details can be found in Table 1.

Chinese Ceramics in Southeast Asia

Tse Siang Lim
Spring Hill, QLD, Australia
School of Archaeology and Anthropology, Research School of Humanities and the Arts, College of Arts and Social Sciences, Australian National University, Canberra, ACT, Australia

Introduction

The trade and export of Chinese ceramics to Southeast Asia have a long history that stretches back into its prehistoric past. To date, the earliest Chinese ceramics found in the region were recovered at Iron Age coastal sites (c. 500 BC–AD 500) in present-day Vietnam and Thailand. Comprising of various lead-glazed and unglazed earthenware sherds, these early Chinese ceramics produced by potters of the Han Dynasty represented the incipient development of a vast "globalized" maritime trading network that connected the late prehistoric region to cultures and polities in South Asia, China, and the Mediterranean world (Carter and Kim 2017). Despite the fall of the Han dynasty and subsequent sociopolitical turmoil that plagued China from the third century AD, maritime trade between China and Southeast Asia – the Nanhai (南海 Nán Hǎi or "South Sea")

trade – continued in the ensuing three centuries, albeit on an intermittent pace and limited scale (Crick 2010c:14–18; Wang 2007 (1958):78–112).

However, only a few sporadic examples of Chinese ceramics of the Yue (越 Yuè) green-glazed typology dating to the Eastern Jin dynasty (AD 317–450) as well as stoneware and white porcelain from the short-lived Sui dynasty (AD 581–618) have been recovered at sites in Sumatra, Java, and Bali (Crick 2010c:18). The reunification and resurgence of China as an imperial power under the Tang dynasty (AD 618–907) however saw the revival of long-distance international maritime trade and exchange akin to that established during the Han dynasty (Crick 2010c:18; Wang 2007 (1958):115). Commonly referred to by historians as the "Maritime Silk Road," the Nanhai trade in this period not only saw regular tributary relations and missions between the Tang court and the polities of Southeast Asia, but also the reestablishment of official relations and missions with the polities on the Indian subcontinent as well as trade with the Persians and Arabs in the Middle East (Crick 2010c; Wang 2007 (1958):115).

Definition

For heuristic purposes, "Chinese ceramics" refer to any form of ceramic artefacts – predominantly vessels – produced by potters and artisans within the geographical boundaries of the present People's Republic of China. Similarly, this entry refers to the geographical region occupied by the ten member states of the Association of Southeast Asian Nations (ASEAN) as "Southeast Asia." Generally speaking, earthenware ceramics refer to any clay artefact fired between 800–1000 °C, stoneware around 1200–1300 °C whereupon clay minerals melt and fuse into a glass-like matrix in a process known as vitrification and porcelain which is achieved through the firing of a mixture of kaolin clay (高岭土, Gāo Lǐng Tǔ) and a non-plastic feldspathic material commonly called "China stone" (白墩子, Bái Dūn Zǐ) at temperatures above 1200 °C (Medley 1976a; Rice 2015:3–6). However, it is worth noting that Chinese potters only distinguish between low-fired earthenware or "Tao" (陶, Táo) and high-fired stoneware and porcelain ceramics which are collectively called "Ci" (瓷, Cí) (Medley 1976a:13–14).

C

Historical Background

Han Ceramics: Third Century BC to Third Century AD

Chinese ceramics stylistically-dated (i.e., distinctive stamped motifs) to the Han Dynasty (Western: 206 BC–AD 220, Eastern: AD 220–280) have been recovered at the site of Suoi Chinh on Ly Son Island off the central coast of Vietnam. Recovered from the Sa Huynh cultural phase (c. fifth century BC to first century AD) at the site, these sherds highlighted the late prehistoric development of maritime trade and exchange along the coast of Vietnam (Pham 2005:136–137). This trade also extended from the coast 115 km to the inland site of Tien Lan, where an imported Chinese bronze bowl was found accompanying a burial (Higham 2014:214). It has since been suggested that Southeast Asian exports such as ivory, rhinoceros horn, feathers, and aromatic wood were traded for Chinese exports including bronze mirrors, bronze bowls, and ceramics (Higham 2014:213–214). Sherds of imported Han dynasty Chinese earthenware were also identified at the coastal site of Khao Sam Kaeo on the eastern shore of the Isthmus of Kra, where maritime trade is thought to have commenced during the early Iron Age (c. fourth to second centuries BC) (Bouvet 2011; Favereau and Bellina 2016:222–225; Glover and Bellina 2011; Higham 2014:231–232).

Fragments of Han earthenware ceramics have also been recovered across various sites in Island Southeast Asia including Sumatra, Java, Borneo, Sulawesi, and Bali (Adhyatman 1990:13; Crick 2010c:14). These vessels are usually lead-glazed or white-slipped with designs painted in "pale shades of black, red or green," and included shapes such as vases, jars, lidded vases with tripod legs, "perfume burners," "ear-cups," lamps, boxes, bowls with handles, as well as spoons

(Crick 2010c:14). As Han earthenware were found in much fewer quantities at these sites as compared to contemporaneous mainland sites in Vietnam and Thailand, it is generally thought that Chinese ceramics were not a significant or regular commodity of trade and exchange in Island Southeast Asia at this time (Adhyatman 1990:18; Crick 2010c:14; Miksic 2009a:71).

Tang Ceramics: Seventh to Ninth Centuries AD

The Nanhai trade between the seventh and tenth centuries AD also saw the large-scale export of Chinese ceramics for the first time in history (Miksic 2009a:72) as well as the transition from the export of earthenware to that of predominantly higher-fired and glazed stoneware ceramics. Three main types of stoneware ceramics were predominantly exported from China in this period: "Changsha" (长沙 Cháng Shā), Yue, and Xing (邢 Xíng) ceramics (Li 2010a:231). Changsha ceramics – eponymously named after the ancient city in the southern Chinese province of Hunan (湖南 Hú Nán) – have been found across various sites in both Mainland and Island Southeast Asia, especially at southern Thailand, the Malay Peninsula and central Java (Miksic 2009a:72). Changsha ceramics were produced at several major kiln complexes about 25–30 km north of the city (Liu 2010:146), and characteristically incorporated a wide variety of forms that included bowls, plates, bottles, vases, handled ewers, rounded bowls, boxes, jars, lamps, and basins (Li 2010a:231); Changsha ceramics in the form of kendis were also reportedly produced and found at various central Javanese sites (Miksic 2009a:72). Also characteristic to Changsha ceramics are the polychrome iron brown and copper green colors typically applied as stylized, pictorial, or calligraphic painted decorations as well as in combination with a variety of appliqué, impressed and stamped motifs (Li 2010a:232). The quantity of Changsha ceramics exported from China in this period was so large that their fragments still "litter the beach" at the site of Laem Pho on the eastern side of the Isthmus of Kra (Miksic 2009a:72).

Yue ceramics are green-glazed ceramics that were produced by kiln complexes located in the Yue Prefecture of the Tang court in the north of present-day Zhejiang (浙江 Zhè Jiāng) province in southern China (Li 2010a:220). Early Yue ceramics (seventh to eighth centuries AD) were produced at varying levels of quality which often results in glazes that were thinly-applied and yellowish green in color (Li 2010a:220). Also characteristic of Yue ceramics are incised decorations of various floral motifs (Krahl 2010b), as well as rings of unglazed spurmarks on both the exterior and interior base surfaces which indicate the use of multiple clay nodules as furniture in the stacking of Yue ceramics for kiln firing (Ho 1994b). Yue ceramic vessels included forms such as bowls, plates, cups, bottles, vases, jar, and handled ewers (Li 2010a:220). Yue ceramics are similarly distributed across various archaeological sites in Southeast Asia, especially in southern China, the Philippines and Indonesia (Ho 1994a).

Xing ceramics typically refers to ceramics which either has a white slip applied over a greyish white body or made entirely out of a pure white paste and, in both cases, bears a layer of translucent glaze (Li 2010a:239). In the former, the vessel color appears white "that was suffused or tinged with yellow," whereas the latter appears in a "glossy" white color that has been noted by Lu Yu (陸羽, Lù Yǔ) in his treatise on tea (茶经 Chá Jīng, c. AD 760–762) lend a "silver and snow" effect in stark contrast to "jade and ice" Yue ceramics (Li 2010a:239). Produced by kilns in the southwestern parts of present-day Hebei province (河北, Hé Běi), Xing ceramic vessels included forms such as bowls, cups, plates, small cups, cup stands, boxes, bottles, vases, handled ewers, jars, pots, tripod platters, and even spouted Buddhist water and ablution kendis and kundikas (Li 2010a:239). Other contemporaneous northern Chinese kiln complexes, notably the Ding (定, Dìng) kilns in the same province and Gongxian (巩县, Gǒng Xiàn) kilns in present-day Henan (河南, Hé Nán) province, also produced "white" ceramics as well (Krahl 2010d).

Other types of Tang ceramics such as the polychromatic Sancai (三彩, Sān Cǎi) and "Dusun" vessels have been recovered from the site of Barus on the west coast of Sumatra (Miksic 2009a:73). Sancai ceramics are lead

glazed earthenware that were produced by a variety of kiln complexes in present-day Henan, Hebei, Shaanxi (陕西 Shǎn Xī), and Sichuan provinces, some of which produced Xing and Gongxian ceramics as well (Li 2010a:249). The intermixing of the four basic glaze colors – white, green, amber, or "reddish yellow" and blue – as they run down the ceramic surfaces during firing (Li 2010a:249–250) resulted in the characteristically colorful appearance of Sancai ceramics. "Dusun" ceramics refers specifically to large green-glazed jars with lugs eponymously named after the ethnolinguistic group in the present-day Malaysian state of Sabah in north Borneo (Kalimantan) where the vessels were first recorded in Southeast Asia (Hsieh 2010a:138). The large Yue green-glazed jars used to store Changsha bowls aboard the Belitung wreck have also been described as "Dusun-type" (Hsieh 2010a:138), and both terms may very well be two separate labels for the same vessel typology.

Song Ceramics: Tenth to Thirteenth Centuries AD

The production and export of Chinese ceramics rose to greater heights during the Song dynasty (c. AD 960–1276) as a direct consequence of the imperial emphasis on maritime trade and exchange as a source of state revenue in the face of threats to the northern frontier and overland Silk Road from the Khitans, Jurchens, and Mongols (Crick 2010c:26; Miksic 2009a:73). Significantly, Chinese historical records on this period such as the Song Shi (宋史, Sòng Shǐ) and the Song Huiyao Jigao (宋会要辑稿, Sòng Huì Yào Jí Gǎo) documents that ceramic goods had become one of the most important maritime exports by the eleventh century AD (Heng 2009:172). Chinese trade ceramics were being shipped overseas *en masse* from the international ports of Guangzhou (广州, Guǎng Zhōu) in Guangdong province, Quanzhou (泉州, Quán Zhōu) and Fuzhou (福州, Fú Zhōu) in Fujian province, as well as Mingzhou/Ningbo (明州/宁波 Míng Zhōu/Níng Bō) and Linan/Hangzhou (临安/杭州 Lín Ān/Háng Zhōu) in Zhejiang province (Heng 2009:19–36). The export of Song ceramics into Southeast Asia appears to have occurred at two levels during this period (Heng 2009:179). The first level involves the production and export of lower quality stoneware ceramics from the southern kilns of Guangzhou and Quanzhou. The second level occurred at kilns that produced higher-quality stoneware ceramics not only for export but also for the imperial court at Jingdezhen (景德镇, Jǐng Dé Zhèn) and Jizhou (吉州, Jí Zhōu) in Jiangxi (江西, Jiāng Xī) province, Longquan (龙泉, Lóng Quán) in Zhejiang province, and Dehua (德化, Dé Huà) in Fujian province (Heng 2009:179).

The mass production of both low- and high-quality Song ceramics at these kiln sites saw the unprecedented distribution and consumption of Chinese ceramics across contemporaneous Southeast Asian archaeological sites (Crick 2010c:32–36; Miksic 2009a:73–78). The quintessential Song ceramic recovered from these sites are green-glazed stoneware ceramics from the kiln complex of Longquan as well as its peers in the present-day provinces of Guangdong and Fujian. Popularly referred to in French as "*céladon*" by art historians, the popularity of Longquan green-glazed ceramics in overseas markets is archaeologically proven. More than 60% of total excavated artefacts between AD 1213 and 1274 at the port of Ningbo consisted of Longquan green-glazed ceramics which became the main export ceramic of Zhejiang province up to the mid-Yuan dynasty (c. AD 1323) (Lin 1994:151–154). Longquan greenware ceramics recovered from the Southeast Asian archaeological context are typically dated to this period (Ho 1994b:191–192), although some relatively "coarser quality" of "Longquan"-type sherds – gritty surface, imperfect glazing and partially or unglazed foot – appears to suggest production and export during the early Ming dynasty in the fifteenth century as well (Kwan and Lam 1985b:123–124).

The Longquan kiln complex is known to have produced numerous green-glazed bowls, large dishes, jarlets, vases, and many other vessel forms between the eleventh and sixteenth centuries AD (Kwan and Martin 1985:77). Early Northern Song Longquan ceramics had thin-walled, white bodies with light green glaze and bore

intricate incised decorations, compared to the thicker, slightly greyish bodies with a yellowish-green glaze that are sometimes crackled and "bold and fluid" incised decorations of the middle and late North Song period (He 2010:298). Decorations on Longquan ceramics are also known to be generally restrained until the middle of the thirteenth century, where they "became more elaborate in technique and frequently more florid in style" (Medley and Pierson 1997:9–10). With the fall of northern China and its capital of Bianjing (Biàn Jīng, 汴京, present-day Kaifeng, 开封 Kāi Fēng) and the relocation of the Song court to the south in Linan in Zhejiang province in AD 1129, the Longquan kilns began to produce high-quality ceramics on par with those produced by the kilns commissioned to produce ceramics for the imperial court (He 2010:301). The adoption of "advanced techniques" of the official kilns also saw the change in clay and glaze recipes that saw the production of high quality, thin-bodied and "deep, limpid" glazed green-glazed ceramics which became popular amongst the southern Song nobility (He 2010:301). Longquan green-glazed ceramics also have a darker green glaze color than its contemporaries from Guangdong and Fujian which has been attributed to the use of coal as kiln fuel in the north (Zhejiang) and wood in the south (Guangdong and Fujian) (Lu 1979:15, 26). The glaze is also thicker and much more opaque due to the application of two or more glaze layers on ceramic body (Kerr 2004:92; Medley and Pierson 1997:9).

Equally popular exports to Southeast Asia are green-glazed stoneware ceramics from the other south Chinese kilns as well (Crick 2010c:33). Green-glazed Guangdong bowls and dishes manufactured between the eleventh and fourteenth centuries AD usually bear a thinly applied light green to green glaze on the body but none on the base or foot of the vessel (Lam 1985:1, 5, 18). Similar green-glazed bowls with combed, incised, and impressed decorations are also produced by many contemporaneous coastal and interior kiln complexes such as Minqing (闽清, Mǐn Qīng), Anxi (安溪, Ān Xī), and Tong'an (同安, Tóng Ān) kilns (Ye 1994:122, 125–126). Kilns in the Quanzhou vicinity reportedly produced "close imitations of Longquan-type glazes, shapes and decoration" specifically for export to overseas markets as well (Ye 1994:122, 125–126), but they can nonetheless be distinguished from Longquan *celadons* through a number of characteristics. Fujian green-glazed ceramics typically bear unglazed stacking rings on their interior bases, a feature not commonly found on Longquan ceramics as most vessels were placed in individual compartments or "saggars" instead of being stacked on top of each other for firing by the thirteenth century AD (Li 1994:89, 95). Fujian vessel forms are also primarily utilitarian – bowls, plates, etc. – and unlike Longquan ceramics, none were ever made for purely art's sake. Just like Guangdong green-glazed ceramics, the glaze on Fujian imitations is quite different from that of Longquan as well. The glaze is generally of a "greyish tone" ranging from yellowish-green to greyish-green in color and not "as neatly and evenly applied" as that of Longquan *celadons* (Ye 1994:123–124). Green-glazed ceramics were also produced at various kilns in present-day Jiangxi, Shaanxi, Henan, Hubei (湖北 Hú Běi), and Hunan (湖南 Hú Nán) provinces as well (Ho 1994c). Nonetheless, they would probably still be transported to the ports designated by the Chinese imperial government for foreign trade and export in Guangdong, Fujian, and Zhejiang (Heng 2009:39, 42–43, 48, 55, 65).

Song ceramics bearing a bluish to greenish white or "Qingbai" (青白, Qīng Bái or, also known as Yingqing, 影青, Yǐng Qīng or "shadowy blue to green") glaze color were also exported to various parts of Southeast Asia as well, albeit at a smaller scale than the popular green-glazed ceramics (Crick 2010c:33–35). Qingbai stoneware ceramics were produced at "forty-four counties of nine Chinese provinces" including Fujian and Guangdong, with those at the Jingdezhen kiln complex of produced Qingbai ceramics of the finest quality and in the greatest number (He 2010:302; Scott 2002:6). Comprising of 136 primary kiln sites, the Jingdezhen kiln complex had access to both high-quality kaolin clay as well as felspathic "China stone" (白墩子,

Bái Dūn Zǐ) that allowed for the production of Qingbai ceramics that resembled "the same colour and texture as jade" (He 2010:302). Early Song Qingbai ceramics were observed to be "mostly plain and undecorated," with only some bowls bearing faint incised or carved decorations of various floral or abstract motifs, as well as the application of dark brown or black iron oxide spots or "splashes" on the exterior surfaces (He 2010:303). Middle Song Qingbai ceramics appeared to have similar forms of decorations, but with thinner bodies, wider rims and smaller feet, as well as glazes that appeared whiter due to a greater control over the kiln firing atmosphere in this period (He 2010:304). Larger quantities of bluish white (as opposed to the greenish white variant) Qingbai ceramics were produced during the late Song period, some of which bear an unglazed rim edge due to the upside-down stacking method of ceramics during kiln firing in order to increase production volume (He 2010:305).

Another famous southern Chinese ceramic production center, the Dehua kiln complex, not only produced Qingbai ceramics but also white stoneware ceramics with a "creamy offwhite tending to yellow or beige" (Guy 1990:71) glaze (also known in French as *blanc de chine*) for export into Southeast Asia as well (Crick 2010d:196–199). Located at Dehua county, the complex had access to rich kaolin clay deposits which were mined and used for ceramic production since the beginning of the Song dynasty (Crick 2010d:196; He 2010:311). With the growing emphasis on maritime trade after retreat of the Song court to the south, the Dehua kiln complex became a major production center for export ceramics into Southeast Asia, producing a wide range of vessel forms including the kundika, ewers, dishes, bowls, and covered boxes (Crick 2010b:196; He 2010:311). Both white and Qingbai Dehua covered boxes decorated with mold-impressed "stylized foliage scrolls" with "rectangular panels with marked ridges and scrolling frieze" (Crick 2010d:196–197, 198–207) in particular are often encountered across various contemporaneous Southeast Asian archaeological sites.

Yuan Ceramics: Thirteenth to Fourteenth Century AD

After the establishment of the Yuan Dynasty (c. AD 1271–1368) in northern China by Kublai Khan in AD 1271, the Mongol emperor embarked on an expansionist policy into the south that eventually saw the demise of the Song dynasty on their last stand at the Battle of Yamen in AD 1279. The cultural and economic importance of Chinese ceramics was not lost to Kublai as he moved to secure and establish his own imperial kiln complex at Jingdezhen in AD 1278 even before he defeated the remnant Song forces in southern China (Barnes 2010:331). The dynasty, however, was short-lived in China and lasted only 97 years before a resurgent Han Chinese dynasty, the Ming, defeated and pushed the Yuan court back north into the Mongolian steppes.

Consequently, most of the Chinese ceramics produced under the Yuan dynasty are represented by the continuation of Song ceramic traditions (Crick 2010c:33). Following the patterns of maritime ceramic trade established in the preceding dynasty, green glazed, Qingbai and white stoneware ceramics alongside brown glazed stoneware storage jars from the southern Chinese kilns in Zhejiang, Fujian, and Guangdong kilns continued to be exported into Southeast Asia (Crick 2010c:33–35). Yuan Longquan green– glazed jars, dishes, and bowls are also observed to be commonly recovered across sites in the Philippines and Indonesia and were specifically used as part of the mortuary assemblage during burial rituals in Sulawesi (Barnes 2010:336). In addition, "iron-spotted" decoration became a popular surface treatment during the Yuan dynasty and was applied to a variety of vessel forms such as small jars and ewers, a number of which were exported to various markets in Southeast Asia (Barnes 2002:130) especially in the Philippine and Indonesian Archipelagos (Crick 2010d:190–193). First developed during the early Song Dynasty, the decorative technique of iron oxide spotting on ceramic vessels was revived during the thirteenth to fourteenth centuries AD and applied on green glazed (also known in Japanese as "*Tobi Senji*"), white and Qingbai

ceramics of various vessel forms (Medley 1976a:152). It has been suggested that the production and export of iron-spotted Qingbai eventually replaced that of plain Qingbai ceramics during the fourteenth century AD (Gotuaco 1997:62, 74).

A new type of white glaze – Luanbai (卵白, Luǎn Bái) – was also developed by the Hutian (湖田, Hú Tián) kiln about 4 km southeast of Jingdezhen (Crick 2010d:153); a relatively "coarser" variant of this glaze is termed Danbai (蛋白, Dàn Dái) (Barnes 2010:367). Both Danbai and Luanbai glaze are "thick, semi opaque and milky" in nature (Barnes 2010:367) which lends a "matt unctuous effect" (Crick 2010d:153) to the white glaze. A number of Danbai and Luanbai white ceramics bear the dual characters of "Shu" (枢, Shū) and "Fu" (府, Fǔ) impressed on the interior wall surfaces together with the decorative motifs, leading them to be commonly called "Shufu" ceramics. It is generally agreed that "Shufu" refers to the Shumi Yuan (樞密院, Shū Mì Yuàn) (Barnes 2010:367; Crick 2010d:153), the Chinese term for the "Bureau of Military Affairs" since its inception during the Five Dynasties Period (AD 907–960). Another set of characters, "Tai" (太, Tài) and "Xi" (禧, Xǐ), which respectively means "great" and "joy" or "happiness" may also be associated with the Taixi Zongyin Yuan (太禧宗禋院, Tài Xǐ Zōng Yīn Yuàn), the bureau in charge of ancestral and ceremonial rites in the Yuan court (Barnes 2010:366; Crick 2010d:153). Despite their strong association with the imperial court, "Shufu" ceramics were found to be exported out of China as Mongol law allowed craftsmen to engage in private trade once quotas have been met (Barnes 2010:366). Commercial "Shufu" ceramics exported into Southeast Asia no longer bore these characters after restrictions on their trade was lifted in 1324 AD and are reportedly "widely distributed" across both the Philippine and Indonesian Archipelagos (Crick 2010d:153).

The spectacular Sinan wreck off the coasts of the southwestern Sinan county islands of the Korean Peninsula provides a rare glimpse into Chinese maritime ceramic trade during the Yuan dynasty. The ship departed from the Zhejiang port of Ningbo (宁波, Níng Bō) around AD 1323 carrying 20,661 pieces of Chinese ceramics, most of which were Longquan green-glazed ceramics and the remaining comprising of Qingbai ceramics from Jingdezhen, black-glazed Jian ceramics, Ding white dishes, and an assortment of ceramics from other kiln sites in Jiangxi, Hebei, Guangdong, and Jiangsu provinces (Barnes 2010:360–362; Lee 2016:223).

Noticeably absent from the Sinan wreck, however, are the renowned blue-and-white stoneware and porcelain ceramics. First produced in China by potters through the import of cobalt from Persia during the Tang dynasty (Krahl 2010c:209), the production of blue-and-white ceramics was revived by the Yuan court sometime between AD 1328 and 1339 a few years after the Sinan wreck occurred (Barnes 2010:369; Crick 2010a:219). Production of Yuan blue-and-white ceramics centered around the Jingdezhen kiln sites of Hutian, Luomaqiao (落马桥, Luò Mǎ Qiáo), and Zhushan (珠山, Zhū Shān), with those produced at the Zhushan kilns reserved for imperial use (Crick 2010a:218). Hutian kilns appear to specialized in the production of large and richly decorated blue-and-white dishes, bowls, vases, bottles, and jars, as well as small dishes, stem cups, and bowls primarily for export, whereas the Luomaqiao kilns appear to produce smaller ceramics with "less sophisticated" decoration for both domestic consumption and export (Crick 2010a:219). Yuan blue-and-white ceramics typically have "rich" but "neat" underglaze painted motifs (裝飾繁縟工整, Zhuāng Shì Fán Rù Gōng Zhěng) of "thick" cobalt blue (青料濃厚, Qīng Liào Nóng Hòu) which is sometimes "uneven" in shade (青花色調濃淡不均, Qīng Huā Sè Diào Nóng Dàn Bù Jūn), as opposed to the "unrestrained" and "lively" brushstrokes (飾紋的用筆奔放、活潑 Shì Wén De Yòng Bǐ Bēn Fàng、Huó Pō) of the Ming period (Yáng and Mǎ 1978:80). The motifs themselves consist mainly of compositions that included floral and faunal designs such as flowers, plants, and animals, as well as traditional Chinese imagery such as dragons, phoenixes, and other mythical animals (Crick 2010a:219–220).

Blue-and-white ceramics exported into Southeast Asian markets are likely to have been

produced at the Hutian and Luomaqiao kilns (Crick 2010a:219). The Daoyi Zhilue (岛夷志略, Dǎo Yí Zhì Lüe) provides the earliest documentary evidence of the export and trade of Chinese blue-and-white ceramics in Southeast Asia. According to its author Wang Dayuan (汪大淵, Wāng Dà Yüan), a Quanzhou traveller in the mid-14th century, blue-and-white ceramics were imported by 15 localities in the region by the mid-fourteenth century AD (Barnes 2010:369) including places on the Malay Peninsula, Singapore, Sumatra, Java, and the Philippines (Miksic 2009a:80–81). Large quantities of Yuan blue-and-white jars, vases, bottles, and large dishes in particular were reportedly found at Majapahit sites in Java, as well as the Philippine islands of Mindanao, Mindoro, Palawan, Cebu, Leyte, and Samar (Crick 2010a:220). Found in much lesser quantities in Southeast Asia – and seemingly mostly in the Philippines (Crick 2010b:212–215; Gotuaco 1997:52, 69) – are "red-and-white" ceramics bearing underglaze copper-red painted decorations similarly produced by the Jingdezhen kiln complex (Barnes 2010:368–369).

Ming and Qing Ceramics: Fourteenth to Nineteenth Centuries AD

With the restoration of ethnic Han Chinese rule under the Ming dynasty in AD 1368, maritime trade was restricted to tributary exchange between the Ming court and foreign diplomatic missions that recognized China's suzerainty (Crick 2010c:37). Private trade with foreigners was limited to the ports of Guangzhou, Ningbo, and Quanzhou, with Ming port officials at Guangzhou and Quanzhou supervising trade with polities in the Philippines, Indonesia, and Indochina (Crick 2010c:37). While a variety of Chinese ceramics continued to be manufactured by Chinese kilns during the Ming dynasty, the overwhelming majority of Chinese ceramics exported into Southeast Asia came to be blue-and-white stoneware and porcelain ceramics (Yoh et al. 2010:556) by the sixteenth century AD.

Restrictions on private maritime trade throughout the fifteenth century AD led to a concomitant shortage of Chinese ceramics in Southeast Asia commonly referred to as the "Ming Gap" (Brown 2009). Based on the ceramic cargo evidence from various Southeast Asian shipwrecks, the proportion of Chinese ceramics fell from 100% to around 30–40% between AD 1368 and 1430 (Brown 2009:69). Proportions fell even further in the ensuing decades to less than 5% by 1487 before Chinese ceramics returned to the Southeast Asian markets during the reign of the Hongzhi emperor (弘治, Hóng Zhì, AD 1487–1505) (Brown 2009:70). A series of sociopolitical disorders and natural disasters that plagued the Ming court between AD 1436 and 1464 that resulted in the disruption of ceramic production is likely to have contributed to the Ming Gap as well (Li 2010b:426–427). A severe shortage of specifically blue-and-white ceramics also occurred between AD 1352 and 1487, where only three examples were found in total aboard a collection of seven shipwrecks (Brown 2009:70). The ban on the production of "colored" wares issued in AD 1437 and 1443 by the Zhengtong Emperor (Zhèngtǒng, 正統) is also a likely cause of the blue-and-white shortage as well (Tan 1997:84). In place of Chinese ceramics, large quantities of Southeast Asian high-fired, glazed ceramics from Vietnamese, Thai, Cham, and Burmese kilns filled most of the ceramic cargo to meet the demand during most of the fifteenth century AD (Brown 1988, 2009).

Consequently, there are very few examples of early to middle Ming (fourteenth to fifteenth century AD) ceramics recovered from Southeast Asia (Crick 2010a:223; Miksic 2009a:84). Nonetheless, a number of early Ming blue-and-white ceramics have been recovered from sites in Indonesia and the Philippines in a variety of forms such as bowls, ewers, kendis, covered boxes, vases, and dishes (Crick 2010a:222, 240–269; Tan 1997:111–156). Painted decorative motifs including landscapes, flora and fauna, Sanskrit characters and Buddhist symbols (i.e., double "*vajra*" and "*makara*"), as well as mythical creatures and human figures are often found on vessels of this period (Crick 2010a:222–223). By the sixteenth century AD, exported blue-and-white ceramics comprised of "robust, thick, utilitarian" vessels that were mainly dishes, but also small platters, cups, bowls, boxes, and jars (Crick

2010a:224). A number of blue-and-white ceramics exported to Southeast Asia during the sixteenth century AD were designs influenced by the emerging Islamic world within the region including "crescent-shaped" kendis and "pear-shaped" ewers (Crick 2010a:224). In addition, the painted decorations of early Ming blue-and-white ceramics are often applied with thick layers of cobalt, causing them to penetrate the glaze and resulting in an uneven surface termed the "heaped and piled" effect (Tan 1997:87).

During the Middle Ming period (fifteenth to sixteenth century AD), the restrictions on foreign trade implemented by the first Ming Emperor Hongwu (洪武, Hóngwǔ) was rescinded in AD 1567 (Crick 2010a:228) and Chinese ceramics returned *en-masse* to the Southeast Asian markets, resulting in the concomitant decline in the trade and export of Southeast Asian ceramics (Miksic 2009a:85). Painted decorations are generally observed to be densely painted motifs that covers the entire vessel surface (Crick 2010a:89, 224). Taoists motifs such as cranes, peaches, Eight Trigrams, and Taoist sages are also commonly found on blue-and-white vessels produced in this time (Tan 1997:92). Underglaze "reign marks" listing the reign of the Ming emperors in cobalt blue are also found on the exterior base surfaces of a number of blue-and-white vessels exported into the region from the sixteenth century AD onwards (Crick 2010a:226; Tan 1997:90; Yoh et al. 2010:560).

Towards the late Ming and early Qing period (sixteenth to seventeenth century AD), Jingdezhen blue-and-white ceramics dominated the production of Chinese ceramics for export whereas Longquan green-glazed ceramics went into decline, leaving white ceramics from the Dehua kilns as the only other major export Chinese ceramic in the market (Yoh et al. 2010:560). The number of kilns also increased drastically – from 20 to 300 by the end of the sixteenth century AD (Crick 2010a:226). Due to a shortage of cobalt oxide from West Asia, during this period, local cobalt pigment was sourced and mined from the eastern and southern provinces of Jiangxi, Anhui (安徽, Ān Huī), Zhejiang, Fujian, and Guangxi (广西, Guǎngxī) (Crick 2010a:228). A new group of blue-and-white stoneware ceramics – popularly known as "*kraak*" – was produced specifically for export to the European markets via the Dutch port-colonies in Southeast Asia during this period (Crick 2010a:229–231). "*Kraak*" ceramics are characterized by decorative motifs composed of "panels radiating from a central circular motif" which are in turn separated by stylized designs such as ribbons and tassels (Tan 1997:95).

In spite of the collapse of the Ming court and the establishment of the Qing dynasty by Manchu forces in AD 1644, blue-and-white stoneware and porcelain remained popular and continued to be produced and exported into Southeast Asia. Blue-and-white ceramics produced by the Pinghe (Pínghé, 平和) kilns near Zhangzhou (Zhāngzhōu, 漳州) city in Fujian Province, in particular, produced blue-and-white ceramics specifically for export (Miksic 2009a:85). Formerly termed "Swatow" ware – after the port of "Swatow" or Shantou (Shàntóu, 汕头) – where they were thought to be exported from (Miksic 2009a:85), Zhangzhou ceramics are typically large plates but also include a range of shapes including bowls, stemcups, jars, vases, and covered boxes that are characterized by large sandy grains adhering to their exterior base surfaces (Miksic 2009a:85). Large quantities of blue-and-white ceramics were also produced by the southern kilns of Dehua, Anxi and Yongchun and exported into Southeast Asia up to the nineteenth century AD (Miksic 2009a:86). Aside from blue-and-white ceramics, the Pinghe kilns also produced many ceramics adorned with overglaze enamel polychromatic decorations most notably in the form of dishes but also bowls, covered boxes, and jarlets (Harrisson 1979, 1995).

Key Issues

Outside the "Pot": Chinese-Style Earthenware Roof Tiles and Kiln Technology

A lesser-known ceramic derivative of cultural contact through trade and exchange between Southeast Asia and China is that of Chinese-style earthenware roof tiles at various late Iron

Age sites along the northern and central coasts of Vietnam (Yamagata and Nguyễn 2010). The centuries following the conquest and reorganization of North Vietnam into imperial prefectures of the Western Han Dynasty around 111 BC (Taylor 2013:17) oversaw a "marked increase" in the production and adoption of "Han-style" artefacts and architecture in the region (Carter and Kim 2017:733). These tiles were produced through using forming techniques that involved molding or coiling with paddle and anvil, both of which being components of *chaînes opératoires* similar to contemporaneous roof tiles that were being produced in China (Yamagata and Nguyễn 2010:195–197). Molded motifs used by the Chinese during the Qin (221–206 BC) and Han Dynasties such as "rolling clouds," lotus patterns, anthropomorphic faces, and Chinese characters were also found adorning eaves tiles on the roofs of northern and central Vietnam. The influence of Chinese culture on ceramic architectural fittings in northern and central Vietnam bears a stark contrast to those found at the Indianized Óc Eo cultural sites on the Mekong Delta in south Vietnam (Yamagata and Nguyễn 2010:196–197).

Both Chinese-style earthenware roof tiles as well as stamped pottery were found to be produced at the kiln complex of Tam Tho in the present-day province of Thanh Hóa in north Vietnam (Hein 2008:13–14; Yamagata and Nguyễn 2010:197). The kiln complex itself is a significant milestone in the history of Southeast Asian ceramic technology, as it represents the earliest datable high-temperature ceramic production site in the region (Hein 2008:13). The establishment of the Tam Tho kiln complex sometime during the second century AD appears to indicate the extension of Chinese commercial interests into late prehistoric Southeast Asia by the Han Dynasty during their occupation of north Vietnam (Hein 2008:13).

Ceramic Time Capsules: The Belitung and Other Shipwrecks in Southeast Asia

The maritime trade and export of Chinese ceramics during the Tang dynasty is perhaps no better represented than the Belitung shipwreck (also known as "Batu Hitam," after the reef about 150 m north of the wreck) recovered off the coast of the main town and port of Tanjung Pandan on Belitung Island in Indonesia (Flecker 2010:101). Approximately 70,000 Chinese ceramic vessels are estimated to have formed the bulk of the cargo of the ship that was identified and dated to be a ninth century Arab sewn-plank dhow (Flecker 2010:101, 107–111). Around 57,000 underglaze copper and iron decorated Changsha ceramics were recovered and comprises of mostly bowls that were packed neatly onboard in both straw containers and large green-glazed storage jars possibly from the Yue kilns (Flecker 2010:109–110; Krahl 2010a:52); Changsha ewers, jarlets, as well as other vessel forms were also found in the cargo (Flecker 2010:107). Yue green-glazed round and square dishes, vases, lug handled basins, bowls were also recovered, as well as medium to large-sized jars which aside from being used as storage for Changsha bowls, were also found to contain lead ingots and star anise as well (Flecker 2010:110). The remaining Chinese ceramic cargo included white Xing and Gongxian ceramics, white ceramics with green-splashed decorations hypothesized to be also produced by the Xing and Gongxian kilns (Hsieh 2010b:167–171) as well as the earliest blue-and-white ceramics produced by the Chinese (Flecker 2010:110).

The discovery of the three Tang blue-and-white ceramics in the Belitung cargo is significant not only because they represent the earliest production of this Chinese ceramic typology but also because they are the first complete examples of Tang blue-and-white ceramics to have been recovered (Krahl 2010c:210). Surviving Tang blue-and-white ceramics in China are rare and fragmentary, with only a small amount of sherds recovered from disparate Tang-period sites such as Yangzhou (扬州, Yáng Zhōu) city in present-day Jiangsu (江苏, Jiāng Sū) province and the Baihe (白河, Bái Hé) kiln site of the Gongxian kiln complex in Henan province (Krahl 2010c:210). Compositional analysis of the cobalt pigment used in the painted decorations suggest an external, west Asian source than local Chinese cobalt sources used in the later blue-and-white ceramics of the Ming (AD 1368–1644) and Qing

(AD 1644–1912) dynasties (Krahl 2010c:210). Aside from the dishes recovered from the Belitung, Tang blue-and-white ceramics incorporated various other forms such as bowls, ewers, boxes, and even pillows (Krahl 2010c:210). A layer of white slip was applied over the "off-white" bodies of Tang blue-and-white ceramics, followed by the painting of cobalt blue decorations that included abstract shapes and floral motifs such as "lozenges" and various foliage similar to those found on West Asian ceramics (Krahl 2010c:210). This decorative similarity, coupled with the absence of Tang blue-and-white ceramics across contemporary land archaeological sites in Southeast Asia, suggests that they were made specifically for West Asian markets (Crick 2010c:24) to which the ship was most likely sailing before it sank (Hsieh 2010a).

Two other wrecks laden with Tang ceramics have also been recovered off the coasts of Indonesia. The first, the Intan wreck, is a Southeast Asian vessel that bore close to 8000 ceramic vessels when it sank south of the Bangka Strait sometime to the tenth century AD (Flecker 2009:38). Almost half of its ceramic cargo consisted of small brown-glazed pots, jars, and basins that are thought to be fired by kilns in the southern Chinese provinces of Fujian (福建 Fú Jiàn) and Guangdong (广东 Guǎng Dōng) (Flecker 2009:38). Around a dozen white jarlets, dishes, and vases likely to be produced by the northern Chinese Xing and Ding kilns, as well as a number of green-glazed bowls, covered boxes and lobed ewers resembling those produced by the Yue kilns accompanied the brown-glazed southern Chinese ceramics (Flecker 2009:38). The remainder of the ceramic cargo comprises of hundreds of fine-paste earthenware bottles and kendis possibly produced by early Southeast Asian kilns located in present-day southern Thailand, as well as a few turquoise-glazed West Asian jars (Flecker 2010:38). The second wreck – also of a Southeast Asian lashed-lugged construction – was discovered off the coast of Cirebon in the Java Sea with more than 150,000 individual ceramic vessels. The vast majority of the ceramic cargo comprised of Yue green-glazed ceramics of a variety of forms including bowls, ewers, covered boxes, jarlets, bottles, cups, vases, and kendis (Liebner 2014). The remaining ceramics included a number of Guangdong brown-glazed jars, Xing or Ding white ceramic bowls, plates, jarlets, as well as earthenware jars and kendis (Liebner 2014) that are likely to have a Southeast Asian provenance.

A number of shipwrecks bearing Chinese ceramics and dating to the southern Song dynasty (c. twelfth to thirteenth centuries AD) have also been located off the coasts of Indonesia and the Philippines (Brown 2009:171). The Java Sea wreck, for instance, bore at least 100,000 individual pieces of ceramics when it sunk off the coast between the Java and Bangka islands (Flecker 2009:39; Niziolek et al. 2018). The vast majority of the ceramic goods consisted of green-glazed bowls and dishes from the southern Chinese kilns in Fujian province, some of which were packed and stored within large brown glaze jars in the manner seen in the Belitung wreck (Flecker 2009:39). Accompanying the green-glazed ceramics are "several hundred" Dehua Qingbai covered boxes, as well as "limited numbers" of Qingbai ewers, bottles, dishes, and lids thought to be produced by the Jingdezhen kilns (Flecker 2009:39). Other Chinese ceramics onboard included black-glazed "*Tenmoku*" – Japanese for iron-glazed tea bowls used by Zen Buddhist temples at Tianmu (天目, Tiān mù) Mountain in Zhejiang – tea bowls possibly produced by the famous Jian (建, Jiàn) kilns as well as a group of bright green lead glazed ewers, bowls, dishes, lids, vases, bottles, and covered boxes thought to be produced by the Chayang (茶洋, Chá Yáng) kilns, both of which are located in Fujian (Flecker 2009:39–40).

Xiaokouping, a Song–Yuan Storage Vessel in Southeast Asia

A distinct Chinese stoneware vessel commonly found across various archaeological sites in Southeast Asia during the Song and Yuan dynasties is the Xiaokouping (小口瓶, Xiǎo Kǒu Píng), popularly called "mercury jar" (Kwan and Martin 1985:74; Wong 2016). The Xiaokouping has a distinctive form: it is a restrictive vessel with a very small rim (c. 1.5–2.5 cm in diameter) set

upon a very short upper body that is only slightly inclined from the horizontal axis, followed by a relatively tall lower body that tapers sharply towards a thick and heavy but also small and flat base (Miksic 1985:68; Wong 2016). The vessel walls bear rilling marks – indicating a wheel-thrown *chaîne opératoire* – that are usually very pronounced on the interior surfaces (Wong 2016). The bodies of Xiaokouping vessel are typically grey in color and contain visible black and white inclusions that results in a rough texture (Kwan and Lam 1985a), but they can sometimes be light brown in color with a smoother surface texture as well. It has previously been suggested that Xiaokouping vessels were produced by the Cengzhushan (曾竹山, Céng Zhú Shān) kilns in Quanzhou (Kwan and Lam 1985a:113; Kwan and Martin 1985:74), but recent research have determined their origin to the Cizao (磁灶, cí zào) kiln complex in the same province (Wong 2016).

The form of Xiaokouping vessels are thought to be "highly suited for carrying mercury," a dense metal in liquid form at room temperature but 13.6 times heavier than water (Treloar 1972:382–383). The thick but small bases allow the jars to support its "great density" as well as divert the "pressure of mercury on diagonally sloping sides of the vessel," respectively, and their relatively tall height coupled with a small orifice would have reduced the amount of spillage during a long land or sea voyage (Treloar 1972:382–383). Moreover, the unglazed surface of mercury jars suit the storage of mercury as it, unlike other forms of liquids, "will not penetrate the most porous vessel" (Treloar 1972:382–383). It was also conjectured that liquid mercury was used in Tantric religious ceremonies, as medicine and a means of extracting gold from its ore or purifying it (Miksic 1985:69). It has also been suggested that Xiaokouping vessels could have been used to store wine and sauces (Kwan and Martin 1985:74; Treloar 1972:378, 383), some of which may have been used to store southern Fujian rice wine in particular (Heng 2009:189; Wong 2016). The widespread use of these jars in Southeast Asia is testified by their recovery not just in Singapore (Miksic 1985:68; Wong 2016), but also in Kedah, Sarawak, and Cambodia at archaeological sites dating between the eleventh and fourteenth centuries AD (McKinnon 1975–1977:76; Treloar 1972:377–378). Xiaokouping vessels were reportedly still used by the Jakun tribe of Orang Asli in Padang Siam, Kuala Seria, and Pahang as late as the twentieth century AD (Kwan and Martin 1985:74).

Chinese Ceramics: Media of Southeast Asian Exchange

Chinese ceramics were not only simply imported commodities but also functioned as media of exchange between Chinese and local merchants in the conduct of trade in precolonial Southeast Asia. Southeast Asian societies adopted monetary standards based on "a directly measurable quantity" of highly valued substances or commodities (Wicks 1992:301). When the Song court banned the export of precious metals such as gold and silver as well as copper cash in AD 1127, 1133, 1175, and 1219, high-fired glazed stoneware ceramics became a commodity-substitute in overseas maritime trade and transactions (Heng 2009:152–172). Ceramics were specifically named as one of the products to be used in place of gold and silver during the 1219 ban (Heng 2009:173).

According to the Zhu Fan Zhi (诸蕃志, Zhū Fān Zhì), a Song record written by the Quanzhou customs inspector Zhao Rugua (Zhào Rǔ Guā, 赵汝适) that described foreign cultures and customs encountered by the Chinese during the thirteenth century AD a century earlier, some Southeast Asian markets appear to have localized preferences towards specific types of Chinese ceramics (Crick 2010c:32). White and green-glazed ceramics were supposedly favored in Borneo, Qingbai ceramics in Java, whereas markets in Sumatra imported a wide range of ceramics without any specific preferences (Crick 2010c:32). In exchange, Chinese traders received from Southeast Asian merchants various aromatic products, spices, and precious items such as pearls, ivory, rhinoceros horns, and other tropical produce needed to satisfy the Chinese market (Heng 2009:191–210). The Daoyi Zhilue compiled by Wang in the mid-fourteenth century, documented demand and consumption patterns of various

Chinese ceramic goods by Southeast Asian markets that were similar to that recorded in the Zhu Fan Zhi (Miksic 2009a:79). During the reigns of the Yongle (永乐, Yǒng Lè, AD 1402–1424), Hongxi (洪熙, Hóng Xī, AD 1424–1425) and Xuande (宣德, Xuān Dé AD 1425–1435) emperors, the Eunuch Zheng He (郑和, Zhèng Hé) led seven naval expeditions through Southeast Asia into the Indian Ocean to establish tributary relations with the polities of these regions (Crick 2010c:37) and was specifically instructed to buy Chinese ceramics to serve as commodities of tributary exchange (Li 2010b:389).

International Perspectives

While the focus on the trade and exchange of Chinese ceramics in Southeast Asia have largely been centered in the core of the region, research on their distribution have also highlighted their demand and consumption in the peripheral parts of Southeast Asia. Chinese glazed ceramics have been found as far as sites in Timor (Glover 1986; Lape and Chao 2008; O'Connor et al. 2012) and even on the northern coast of Australia (Macknight 1976, 2013). Chinese ceramics from "southern China," in particular, were reportedly found and identified "on many sites" in Arnhem Land as part of the trepang trade between the Chinese, Macassan, and Australian Aboriginal groups during the eighteenth century AD (Macknight 2013:25–26). Research on the distribution of Chinese ceramics on the Southeast Asian periphery, however, remains in its infancy.

Future Directions

Chinese Ceramics and Social Organization in Southeast Asia

Presently, the focus of historical and archaeological analyses of Chinese ceramics from both land and maritime archaeological contexts in Southeast Asia remains overwhelmingly on their utility as evidence of trade and exchange between China and various Southeast Asian polities over the last millennia. The significance of Chinese ceramics in the social organization and political economies of Southeast Asian societies (see Junker 1999), however, remains relatively understudied in both history and archaeology. As trade routes were established between Southeast Asian and Chinese markets over the centuries, Southeast Asian elites found a new source of high-quality and beautiful glazed and unglazed stoneware as well as porcelain ceramics that they did not have the technology to produce. Imported Chinese ceramics, such as small vessels with lids, came to be considered a luxury suitable for use only by the Khmer nobility in the eleventh century (Miksic 2009a:78). Chinese porcelain, among other exotic luxury goods, also became "key symbols of social status and political power" together with indigenously manufactured prestige goods for the chiefly elite in the Philippines (Junker 1999:183). The symbolic significance of Chinese ceramics can also be seen at the two-level hilltop fortified site of Macapainara in Timor, where a "Chinese blue and white tradeware bowl" was found to be placed on the surface of a large stone structure on the lower level of the site, and identified by local inhabitants as the "double grave containing the remains of the former ruler of Ili Vali/Macapainara and his close political ally" (O'Connor et al. 2012:204–205).

Chinese Field Methods

Liangren Zhang
School of History, Nanjing University, Nanjing, Jiangsu, China

Introduction

Although the study of ancient artifacts has a long history in China, the modern science of archaeology was brought to China only in the late nineteenth century by foreign explorers and archaeologists. Since the 1920s, however, as the Nationalist government curbed foreigners' field activities in its land, native archaeologists, mostly Western-trained, from a few institutions (the Cenozoic Research Laboratory of the Geological Survey of China, the Institute of History and Philology of Academic Sinica, and the Society for Historical Studies of National Beiping Academy) began to play the major role (Chen 1997: 87). The political fragility and economic feebleness of the time, however, did not allow the science to

develop significantly. Although much progress was made in excavation techniques, including the division of strata and typological analysis of artifacts (Chen 1997: 145–162, 227–249, 310–329), only a modest number of sites had been excavated and a small group of archaeologists had been trained by 1949, the year when the Communist Party took over the mainland China.

Dramatic changes came about after 1949. Having unified the country, the communist government set out to modernize its industry, science, and education. And having decided to dissect its relations with the West and sided with the Soviet Union, it urged the academic community to learn the "advanced experience" of the Soviet science. The archaeologists and their students, who were trained in the West or educated in the pro-West Nationalist Era, had little choice but to study Soviet theories and methods (Zhang 2011: 1052). Archaeology, which now received lavish state support, continued to be cast as a subdiscipline of history as in the Nationalist Era, but upon it was already imposed a new paradigm: Marxist dialectical materialism and historical materialism. While dialectical materialism introduces the concept of social evolution, historical materialism brings the subjects of social relations, economy, and technology to archaeology (Xia 1952: 81–84). The Soviet archaeology also demands that archaeologists devote themselves to the life of the subject and downtrodden people, as a counterforce to their natural instinct, that is, to excavate tombs and monuments of the social elites. It does not follow, however, that Chinese archaeologists give priority to settlements and tombs of the common people. In fact, apart from a few exemplary Neolithic settlements that were dug to fulfill the Marxist mandate, they continue to favor large urban centers, such as Erlitou, Anyang, Luoyang, and Chang'an, and monumental tombs for the purpose of uncovering treasures and wonders to illustrate the grandeur of Chinese history and civilizations (Zhang 2011: 1052).

Key Issues/Current Debates/Future Directions/Examples

Chinese archaeologists translated many Soviet publications to avail themselves not only of ready-made models of integrating the Marxist theories into archaeological interpretation but also of "advanced" fieldwork methodologies. As a result, they began their fieldwork with systematic survey, thereby acquiring the basic information of the location, chronology, and cultural definition of a single site as well as informing questions such as the geographic distribution and the ecological environment of a culture (Xia 1958: 2). In addition, Chinese archaeologists innovatively adopted the "Luoyang Spade," a coring device which local treasure hunters had developed to discover tombs, as a prospecting tool. Skilled hands were trained to identify various types of features (tombs, architectural foundations, trash pits, riverbeds) from the soil samples taken from underground. Thanks to its efficiency and low cost, the tool is still popular today; one can often use it to get a good idea of the layout as well as stratigraphy of a site without excavation.

When Chinese archaeologists excavate a settlement, they usually lay out box pits of 2×2 m, which they replicate to expose large areas (Fig. 1). This method is very helpful because many settlements in China feature long habitation history and multi-period cultural deposit. Although it had also been used in the West, they were obliged by the ideology of the time to attribute the credit of inspiration to the Soviet archaeologist T. S. Passek (1903–1968). While earlier excavators were unable to discover houses at the Tripoly'e settlement because they had only opened narrow trenches and small areas, in the 1930s, Passek successfully discovered structures of 100–120 m^2 in dimension with the box excavation. In a country blessed with long history and thick cultural deposit, this method appears to be very useful, as it provides a better stratigraphic control and a better understanding of a settlement: division of space and episodes of reconstruction

Chinese Field Methods, Fig. 1 The "small unit/large exposure" (box system) in action on an excavation in advance of road building at Baotou, Inner Mongolia in 2006 (China, State Administration 2009)

(Yan 1994: 252). Dubbed by Chinese archaeologists as "small excavation units but large-scale exposure," it was put to good use at the model Neolithic settlement of Banpo near Xi'an and Jiangzhai (Zhongguo Kexueyuan KaoguYanjiusuo 1963: 6; Banpo Museum, Shaanxi Institute of Archaeology, and Lintong County Museum 1988: 3–5). While the size of the unit is often adjusted to the specific circumstances and objectives of an excavation (it is now usually 5 × 5 m or 10 × 10 m), the box pit excavation remains the standard operational method today (Shi 1982: 18–19).

Ancient cities, especially those of the protohistoric and historical periods, demand a different approach. Following the Soviet guidelines, Chinese archaeologists first study historical documents to address questions about material production, social relations, and the spiritual life of the population. They can then turn to other questions such as spatial division, public amenities, and external economic connections. Since cities are much larger and more sophisticated than Neolithic settlements, it is unrealistic to implement the full-coverage excavation; small excavation units are instead deployed at particular loci to address particular questions, such as layout and chronology. Three phases of deposit are generally investigated to define their chronology: those formed during construction, those formed during occupation, and those after abandonment. This set of methods was effectively applied to the excavation of Chang'an, a capital of the Western Han Dynasty (206 BCE–9 CE), near the present-day city of Xi'an. Together with the method of dividing cultural strata by soil content and color, it is still cherished as a working principle today (Zhang 1983: 62).

Regional Genealogy and Variations

The intense learning of the Soviet archaeology came to a halt after the breakup of the Sino-Soviet brotherhood in the 1960s. Having turned away from the West in 1949, Chinese archaeologists were now secluded from the development of archaeological theories and methods over the world. Without external inspiration, they were left to move forward from what they had inherited from the Nationalist Era and learned from the Soviet. In the volatile political atmosphere that lingered from the 1950s through to the 1980s, however, theoretical thinking, even in the name of Marxist theories, was a life-threatening venture. Hence, no middle-range theories and methodologies were developed to extrapolate the Marxist subjects of social relations, economy, and technology; discussion of these subjects was little more than filling fresh data into the old pigeonholes of Marxist theories. It was the typology and cultural-historical paradigm inherited from the Nationalist Era, safeguarded by the sustained nationalism, that had the chance of further development in the subsequent decades.

It was Su Bingqi (1909–1997), a courageous thinker for his time, who held the beacon for theoretical development in China. He began his theoretical venture in the 1930s when he attempted to work out a chronology for the Bronze Age cemetery at Doujitai in Baoji, Shaanxi Province. Employing Montelius' typology but tempering it with his own interpretation, he selected the diagnostic ceramic ware li-tripods as the subjects of typological analysis, divided them into four types, and traced each type's evolutionary path (Su 1948 [1984]). Since the 1950s, the division of xing (type) and shi, which stands for the chronological subtype, became the standard method in Chinese typology (Su 1959 [1984], 1965). This method was further refined to fit the ever-growing excavation materials by Su Bingqi himself and his disciples. In his endeavor to set up chronologies for the Shang urban centers of Zhengzhou and Anyang, Zou Heng (1956, 1964) innovatively correlated stratigraphic and typological sequences of ceramic wares from these sites.

Su Bingqi's creativity did not end up at the typological analysis. He further developed a theory, namely, the "regional genealogy and variations (quxileixing)," that offers a handy framework for organizing and explaining them (Su and Yin 1981; Su 1982). In this general and flexible formulation, the archaeological cultures that had been discovered by the 1970s were grouped into six macroscopic cultural-historical regions; each region comprises of a few micro-regions, whose cultures are lined up from the Paleolithic Age through to the Bronze Age. Rejecting the conventional assumption that Central China was the cradle of Chinese civilizations lifting the outlying regions from backwardness, he emphasized instead that it was the outlying regions that outshined and enlightened Central China in the Prehistoric periods. Believing in the historicity of traditional texts, he further linked some of the regional cultures with early ethnic groups recorded in these texts (Su and Yin 1981; Su 1982).

New Development

The typological analysis and the "regional genealogy and variations" theory were imbued into a national fieldwork manual issued in 1984 (Ministry of Culture 1984). Su Bingqi and his disciplines, all prominent figures in Chinese archaeology, frequently traveled across the nation to deliver them to their fellow colleagues and urged them to mend up the gaps of the cultural lineages of their regions. Blessed by the growing excavations since the 1970s, each province was able to write its cultural history, more or less complete, from the Paleolithic Age well into the historical periods (Wenwu Editorial Committee 1979, 1991). They nevertheless brought much harm to Chinese archaeology in the meantime. Emphasizing on the importance of stratigraphy and cultural sequence, they ignored many of other questions, such as settlement pattern, and subsistence economy, as well as many types of data, such as soil, food residue, and botanical and faunal remains.

Since the late 1970s, however, China reopened itself to the World and once again appreciated foreign archaeological theories and methods, mostly of the West and Japan. In 2005, the State Administration of Cultural Heritage (SACH) commissioned the Archaeology Department of Beijing University, the leading institution in China, a major revision of the 1984 manual to catch up with the current development in archaeology over the globe. From manuals of Britain and Japan, the new manual, which was issued in 2009, adopts the social archaeology of the West and the research subjects of settlement pattern, subsistence economy, craft production, and social organization. It asks excavators to pay attention not only to stratigraphy but also to spatial organization and formation process of a site. It inserts sifting and flotation facilities into the excavation process so as to gather tiny animal bones, plant seeds, and artifacts for future analysis. In addition, it demands on-site conservation for the purpose of protecting fragile artifacts and features (SACH 2009). In line with the new standards, an excavation project is no longer targeted at narrow subjects such as chronology and cultural definition, but becomes a platform for multidisciplinary cooperation; it is no longer a closed domain for the excavators alone, but an open territory for many specialists who examine various types of

materials. In this way, Chinese archaeology will surely interact with the world communities more actively in the future.

C

Chinese Porcelain: Late Ming (1366–1644) and Qing (1644–1911) Dynasties

Teresa Canepa
London, UK

Brief Definition of the Topic

In the late Ming dynasty, porcelain was manufactured in the city of Jingdezhen, the largest and most important kiln complex in China, situated in the northeast of Jiangxi province. Porcelain was already being manufactured in the city in the Song dynasty (960–1279), but it was not until the thirteenth century during the Yuan dynasty (1279–1368) that the imperial or official kilns (*guanyao*) were established to manufacture porcelain of the finest quality and most advanced technology exclusively for use by the Emperor and the court at the capital in Nanjing. The Emperors of the succeeding Ming dynasty (1368–1644), who after 1420 ruled from the new capital situated further to the north in Beijing, required annual orders of hundreds of thousands of porcelain pieces made in a wide range of shapes, which were often beyond the production capacity of the kilns under imperial supervision. Consequently, a number of privately owned kilns (*minyao*) located in and around Jingdezhen had to fulfill some of the porcelain orders for the court, as well as to manufacture porcelain for both the domestic and export markets. The porcelain made in the early Ming dynasty was mostly decorated in underglaze cobalt blue using high-quality cobalt imported from Iran (Harrison-Hall 2001).

By the late Ming dynasty, when the Emperors Jiajing (r.1522–1566), Longqing (r.1567–1572), and Wanli (r.1573–1620) ruled China, the imperial kilns had entered into decline due to a lack of financial resources and corruption and after repeated riots had to be closed in 1608. As a result, the best porcelain potters and painters went to work at the private kilns, bringing with them the technical expertise formerly monopolized by the imperial kilns. They were now free from strict official constrains, and thus innovation followed (Canepa and Van der Pijl-Ketel 2008). Although the majority of the porcelain was decorated in underglaze cobalt blue, using a mixture of the high-quality cobalt from Iran and the cobalt that was being sourced from western China since the early fifteenth century, the kilns also manufactured porcelain decorated in polychrome overglaze enamels in the sophisticated techniques of *doucai* and *wucai* (five colors), as well as *kinrande* (gold brocade) (Canepa 2016).

China had been exporting a variety of ceramics to Southeast Asia, the Middle East, and Africa since the ninth century. A small number arrived to Europe in the fourteenth century, but it was not until the mid-sixteenth century that the Portuguese began importing large quantities of porcelain into Europe via their newly established long-distance sea trade routes to Asia. This is attested by the porcelain cargo yielded from homeward-bound Portuguese shipwrecks, which consisted predominantly of blue-and-white porcelain made for export at private kilns in Jingdezhen ranging from high to medium quality, all with purely Chinese forms and decorative motifs derived from nature with Buddhist, Daoist, or Confucian connotations and a variety of flowers, fruits, and scroll borders, as well as a small quantity of porcelain decorated in overglaze enamels. These archaeological finds reflect the significant increase in porcelain production at Jingdezhen during the 44-year reign of the Jiajing Emperor, not only for the imperial court and domestic market but also for the export market, which led to a far greater variety of new shapes and decorative motifs and techniques (Canepa 2014, 2016).

By the late sixteenth century, a new style of Jingdezhen blue-and-white porcelain known as *kraak* was being manufactured in vast quantities at several private kilns in Jingdezhen almost exclusively for export. It seems likely that the development of this new export porcelain was prompted by the lifting of the Ming maritime trade ban by Emperor Longqing when he ascended to the throne in 1567. *Kraak* porcelain was thinly potted and densely decorated in a free and spontaneous style with traditional Chinese auspicious animals and Buddhist, Daoist, and Confucian motifs or narrative scenes taken from novels or other literary works. This porcelain, made throughout the reigns of Emperors Wanli, Tianqi (r.1621–1627), and Chongzhen (r.1628–1644), was adapted to the taste and specific demands of its overseas customers in Japan, Southeast Asia, the Middle East, and Europe. This led to the introduction of a wide variety of new shapes and decorative styles, some of which were made after European models and designs (Rinaldi 1989; Cao and Yi Fei 2006; Canepa and Van dep Pijl-Ketel 2008; Canepa 2012, 2016; Ströber 2013). Although the decorative styles of *kraak* porcelain changed over time, its characteristic decoration arranged into panels remained popular for several decades and thus was imitated at the private kilns of Zhangzhou in the southern province of Fujian (Canepa 2010). By the late 1570s, *kraak* and other fine late Ming porcelain from Jingdezhen, as well as the somewhat coarser Zhangzhou porcelain, were exported throughout the world. This was possible first through the sea routes of the Iberian kingdoms of Portugal and Spain and then also by the trading companies formed by the Northern Netherlands/Dutch Republic and England that connected Asia with both Europe and the New World (Kuyamama 1997; Canepa and Van der Pijl-Ketel 2008; Canepa 2012, 2014, 2016; Van der Pijl-Ketel 1982; Kerr et al. 2011; Ströber 2013).

A variety of blue-and-white porcelain pieces decorated in a new painting style, the so-called transitional, began to be manufactured at the private kilns of Jingdezhen in the reign of Emperor Tianqi and continued into the subsequent reign of Chongzhen, during the unstable and politically chaotic transition period, which occurred at the end of the Ming dynasty and the rise of the Qing dynasty (1644–1911). This high-quality porcelain

was intended for both the domestic and export markets (Butler et al. 1990; Butler and Qinzheng 2006; Huang 2009/2010). By the late 1630s, it was imported, alongside *kraak* and small quantities of Jingdezhen porcelain decorated with overglaze enamels and *kinrande*, as well as the pure white porcelain, known by the French name *blanc de chine*, manufactured since the mid-Ming dynasty at the private kilns of Dehua in Fujian province, into both Europe and the New World (Kerr et al. 2011; Canepa 2016).

After the imperial kilns were reestablished in the early Qing dynasty, a variety of new decorative techniques and schemes were developed. A large quantity of the porcelain manufactured in or around Jingdezhen during the reigns of Emperors Kangxi (r.1662–1722), Yongzheng (r.1723–1735), and Qianlong (r.1736–1795), when the East India Companies (Dutch, British, French, and Swedish) dominated the sea trade with China, was delicately painted in underglaze cobalt blue. But there was also porcelain that combined the use of underglaze cobalt blue with overglaze enamels and porcelain decorated in *famille verte*, *grisaille*, Chinese Imari (imitating the decorative style of Japanese Imari), and *famille rose*. As the quantities of the porcelain orders increased, the enameling work moved from Jingdezhen to Canton (present-day Guangzhou) in Guangdong province, where low-temperature muffle kilns fused the overglaze enamels onto already fired pieces. This *chine de commande* porcelain was decorated with elaborate European designs that were based on prints and drawings sent by European traders. The Americans, who arrived in Canton in 1784, put an end to the trade dominance of the East India Companies. The European trade in *chine de commande* porcelain continued in the reign of Emperor Jiaqing (r.1796–1820), but exports to the West started to decline by the 1830s, during the subsequent reign of Emperor Daoguang (r.1821–1850) (Staniforth 1996; Leath 1999; Kerr et al. 2011; Lucas 2006). The late Ming and Qing porcelains discussed above bear witness to the continuous commercial, cultural, and artistic exchanges that occurred between the East and West, which lasted three centuries (from the sixteenth to the nineteenth century).

Chiripa and the Emergence of Social Complexity in the Lake Titicaca Basin

José M. Capriles
Department of Anthropology, The Pennsylvania State University, University Park, PA, USA
Instituto de Investigaciones Antropológicas y Arqueológicas, Universidad Mayor de San Andrés, La Paz, Bolivia

Introduction

Chiripa is an archaeological site that has been fundamental for discussing key processes of cultural change in the New World and particularly in the Lake Titicaca basin of the south central Andes (Hastorf 2008; Mohr-Chávez 1988; Ponce 1970; Stanish 2003). Contemporary to Qaluyo and predating other important developments such as Pukara in Peru and Tiwanaku in Bolivia, research in Chiripa has been key for discussing a wide range of topics including early village life, plant domestication and agricultural intensification, human responses to climate change, social complexity, and primary state formation. The site exemplifies the "Formative Period" of the Lake Titicaca basin, associated with the adoption of ceramics, sedentism, and agriculture, and has been systematically investigated by successive generations of archaeologists applying innovative documentation and recovery protocols for their time. Although there are still many unresolved questions surrounding the people who inhabited it, Chiripa is arguably one of the best investigated sites in the Andes.

Definition

Similarly to other archaeological sites, the term Chiripa has been used to refer to a ceramic style, a series of cultural phases, and a cultural complex in addition to its modern use which refers to a hacienda or plantation that was dissolved into a presently exiting Aymara community following the Bolivian agrarian reform of 1953. Nevertheless, Chiripa basically refers to an archaeological site situated in the southeastern shore of Lake Titicaca in the department of La Paz of modern-day Bolivia. More precisely Chiripa is located on the northern shore of the Taraco Peninsula, lays over a colluvial terrace, and sits between a series of small seasonally activated streams. The entire landscape is occupied by small and parceled cultivated or fallowed fields of potatoes, quinoa, fava beans, barley, maize, and other annually rotating crops (Bruno 2014).

The site of Chiripa covers approximately 25 ha (−16.4332, −68.8308, 3860 m above sea level). Its center consists of a roughly rectangular raised platform mound (locally known as montículo), which measures approximately 60 × 55 × 4 m, oriented geographically north-south, and which contains a sunken court temple surrounded by a series of rectangular buildings (Browman 1998). The walls of the sunken court measure approximately 24 × 26 m and consist of cut sandstone and limestone pillars or standing stones filled-in between them with smaller uncut and partially cut stone blocks (Fig. 1). The sunken court temple is trapezoidal and was remodeled several times throughout its life use. One of its latest iterations is exposed and was reconstructed in 2006. Behind the four walls of the sunken court, there are between 14 and 16 rectangular structures with double walls, bins, and (sliding) doors oriented toward the court and organized in an octagonal pattern. One of these structures was partially exposed in 2006 and is currently covered by a glass structure. The entrance to the court was possibly situated in the northern wall, accessed from the lake. In addition to the stone pillars, a number of stone monoliths have been unearthed at the site. The sculptural style of the monoliths features iconographic representation of snakes,

toads, lizards, spirals, camelids, crosses, and anthropomorphic figures with exaggerated appendixes suggesting fecundity.

Research History

Wendell C. Bennett carried out the first archaeological excavations at the site in 1934 and identified the salient features of the site including the sunken court and the surrounding rectangular buildings (that he interpreted as "houses"). The buildings were composed of adobe and stone cobbles, as each included a central sliding door oriented toward the court (Bennett 1936). These structures included inner and outer walls, which contained a series of separated peripheral compartments or bins accessible to the central room by small window niches neatly decorated with stepped motives and lintels. Bennett partially exposed the northwestern corner of the court and the two buildings that lay to its sides in a long trench. The buildings he encountered included remarkably well-preserved adobe, quinoa grains, and *chuño* (freeze-dried potatoes) in these bins. Beneath the buildings, he encountered a series of cist tombs, some of which contained small gold plaques and other smaller offerings. Bennett also documented a "pre-house" cultural level that anteceded the construction of these structures. Interestingly, Bennett (1936) initially described Chiripa ceramics occurring after Tiwanaku, a mistake he subsequently corrected.

Shortly after Bennett's work, Maks Portugal Zamora and María Luisa Sánchez Bustamante complemented excavations at the mound including exposing other similar buildings and burial features. Alfred Kidder II directed excavations at Chiripa in 1955 following his extensive research at the site of Pukara in the northwestern side of Lake Titicaca. Unfortunately, a synthetic report of this work was never published (Kidder 1956;

Mohr-Chávez 1988). Perhaps the most important result of this project was the collection of charcoal samples for radiocarbon dating, which verified the temporal precedence of Chiripa before Tiwanaku. Based on this accumulating evidence, Chiripa and Wankarani (another Formative development mostly situated in the Oruro department of Bolivia) have been described as the village phase that preceded the development of the Tiwanaku state (Ponce 1970).

In the 1970s, David L. Browman carried out large-scale research in Chiripa. Most excavations were focused on the sunken court temple, but additional areas were also tested (Browman 1998). The results of his findings helped to improve the chronology of the site, discuss the role of exchange of foreign resources, and propose a series of hypotheses regarding the Formative Period's economic, social, and political organization. This project involved the implementation of fine-recovery protocols including the recently developed water flotation system for recovering macro-botanical and microfaunal remains. From his excavations, we learned much about the central court.

Since 1992, Christine A. Hastorf has directed the Taraco Archaeological Project (TAP), which involved several excavations seasons at Chiripa, including ongoing research focused on expanding the understanding of the site and the daily life of its inhabitants. TAP's excavations at the site itself included work on the mound as well as testing and exposing large operations in new complexes including Llusco, Choquehuanca, Santiago, and Quispe (Hastorf 1999, 2003, 2008, 2012). Interdisciplinary analysis of the recovered materials complemented by numerous radiocarbon dates has helped to improve the chronological and socio-cultural framework of the site. In addition, a systematic survey of the entire Taraco Peninsula was carried out including the systematic collection of artifacts from the main Formative Period sites (Bandy 2004). In addition to TAP's work, between 2005 and 2007, the Bolivian government carried out an excavation and restoration project at Chiripa (PACH), which involved reconstructing the sunken court and exposing and protecting one of its surrounding structures (Fig. 2).

Because of its gentle topography, the Taraco Peninsula lacks the impressive terraces found elsewhere in the lake, yet the entire landscape has been transformed by successive generations of farmers who have slowly transformed it into an

Chiripa and the Emergence of Social Complexity in the Lake Titicaca Basin, Fig. 2 The Chiripa sunken court viewed from the southeast in November 2013. The steel and glass structure visible behind the north wall protects one of the surrounding rectangular buildings

agrarian landscape (Bruno 2014). How were these activities related to the settlement is part of ongoing research. The study of contemporary community practices including ethnobotany, land use management strategies, and resource utilization sustainability are the focus of TAP's recent work in collaboration with the local community and Bolivian research institutions.

Chiripa During the Formative Period

During the Early Formative Period (1500–800 B.C.E.) Chiripa was initially founded as a small village of farmers, herders, and fishermen. The beginnings of the site coincided with increased regional humidity and the transgression of the smaller portion of Lake Titicaca, following an arid period that persisted during much of the middle Holocene (Baker and Fritz 2015). Throughout the subsequent centuries, regional climate fluctuated producing important consequences on the economy of the societies settled around Lake Titicaca (Capriles et al. 2014). Chiripa grew progressively and extensively, and economic, religious, and political activities left a complex record of architectural features, feasting trash deposits, and funerary tombs of various styles. During the Middle Formative Period (800–100 B.C.E.), the raised platform mound was built including the sunken court and its surrounding structures (Hastorf 2003). During this time, the site acquired its largest expanse, and yet it hardly exceeded seven hectares of extension (Bandy 2004). The site, however, grew in internal complexity and most of the central portion of the site was built and rebuilt several times adding a series of sunken enclosures.

During the Late Formative Period (100 B.C.E.–500 C.E.) and subsequent Tiwanaku Period (500–1100 C.E.), the site waned in regional importance, initially depending on Kala Uyuni (a site roughly situated 10 km west of Chiripa) and eventually to Tiwanaku, but the remodeling episodes associated with its sunken court persisted until the site was abandoned altogether.

The Chiripa ceramic style includes a diversity of mostly fiber-tempered wares mostly represented in bowls and ollas with various rim and neck types. The finest vessels (including some unique ceramic trumpets) are finely burnished, include cream- over red-painted stepped designs, and occasionally bear plastic decoration of feline motives. The economic base was diversified and consisted of mixed quinoa and potato farming with llama and alpaca pastoralism, fishing, hunting fowl and other small fauna, and the collection of aquatic and terrestrial plants. Paleoethnobotanical research has allowed to identify increased selection of quinoa seeds with thinner testa as an attribute directly associated with artificial selection in the context of plant domestication but also agricultural intensification (Bruno 2014; Hastorf 2012).

Beyond the raised platform mound, Chiripa comprises a series of additional rectangular and trapezoidal buildings, burials, middens, and other domestic and ritual features (Hastorf 1999, 2003, 2008, 2012). Archaeological survey and excavations in nearby sites suggest that the sequence observed in Chiripa is a good reflection of the trends that occurred regionally in terms of demographic, environmental, and sociopolitical change (Bandy 2004). Dozens of contemporary sites with similar, albeit slightly different features, are distributed along the shores of Lake Titicaca and include Achachi Coacollo, Alkamari, Alto Pukara, Ch'issi, and Pajchiri (see Stanish 2003). Before the emergence of chiefdoms or "multi-community" polities in the Late Formative Period, most of these sites including Chiripa were part of economically and politically autonomous communities (Bandy 2004).

Key Issues and Current Debates

The data produced in the context of investigating Chiripa and contemporary Formative Period sites in the Titicaca basin has been used to discuss a number of important research topics including the emergence of social complexity, early village life, household organization, plant and animal domestication, fishing, and the impact of humans in the Lake Titicaca ecosystem, among many others (see Hastorf 2008; Stanish 2003). Relevant to all of

these themes is how the site itself evolved and changed in relation to intrinsic (demography, agricultural intensification, craft specialization, political centralization, religiosity) and extrinsic (migration, climatic and environmental change) factors. For instance, it is not entirely clear if Chiripa and other contemporary agricultural villages evolved from previous hunter-gatherer communities or if they were part of a broader migratory process by emergent agriculturalists. Given that no Archaic Period hunter-gatherer sites have been discovered in the Taraco Peninsula, it remains to be determined if their absence is a product of sampling intensity, taphonomy, low hunter-gatherer population densities, or environmental factors that made the region unattractive to foragers before the late Holocene but subsequently quite attractive to early agro-pastoralists.

A related question is how the demographic growth trend observed in the following millennia was related to environmental change, agricultural intensification, or an increasingly sophisticated institutional framework. In other words, was population growth a consequence of improved climatic conditions, cascading effects of technological innovations, or the enforcement of specific social sanctions? Moreover, we know that the shores of Lake Titicaca have fluctuated considerably over time, in part due to complex climatological and environmental processes, but the precise interconnection between climate, demography, and human adaptive strategies is still under discussion (e.g., Capriles et al. 2014). Ongoing paleolimnological work to improve the resolution and precision of the currently available lake level reconstructions will aid considerably in resolving this debate (Baker and Fritz 2015).

In the Lake Titicaca basin, the persistence and transformation of sunken courts and surrounding structures such as those featured at Chiripa have been used to support the evolution of a long-term tradition of corporate monumental architecture (Mohr-Chávez 1988). For instance, stone monoliths and sunken courts similar to those at Chiripa are present in contemporaneous sites on the Copacabana and Santiago de Huata peninsulas and later Late Formative sites such as Khonkho Wankane, Pukara, and then Tiwanaku. Therefore, the "Yaya-Mama Religious Tradition," defined by the presence of temples with storage features, stone sculptures of supernatural beings, ritual paraphernalia including ceremonial burners and trumpets, and iconography featuring rayed appendixes and divided eyes, has been proposed to characterize the similarities shared among these Formative sites (Mohr-Chávez 1988). Nevertheless, the existence of a religious tradition does not in itself explain the differential trajectories of change observed between different settlements. Inter-societal competition, violence, exchange, and cooperation in a context of demographic growth should also be accounted for in explaining the emergence of social complexity in the Lake Titicaca basin (Stanish 2003). Regional investigations have discarded that strong sociopolitical integration occurred during the Early and Middle Formative periods, but differential investment in monumental corporate architecture occurred in various sites. In fact, the Tiwanaku state (which consolidated some of these processes) emerged fundamentally based on the religious, institutional, and economic integration developed from earlier times.

In this debate, archaeological questions such as the specific function of the complex structures that surround the Chiripa sunken court (and similar ones across the region) become gradually relevant. Initially these buildings were interpreted as houses; however their location, form, appearance, and content also supported a non-domestic, more communal role (Bennett 1936; Kidder 1956; Ponce 1970). It was later proposed that these structures were part of a ritual complex that involved agricultural rites and storage of offerings in the context of the Yaya-Mama Religious Tradition (Mohr-Chávez 1988). On the other hand, considering that under the floors of many of these structures, a series of human burials with offerings have been documented, the compartments might have served as niches to house burials similarly to the better known Late Intermediate Period burial towers known as *chullpas* (Hastorf 2003). This proposition implies that the entire complex might have been related to an ancestor cult that legitimatize land tenure, use of the landscape, and fostered social cohesion on the peninsula. Nevertheless, the association between

these burials and the surrounding structures is not supported by robust contextual evidence as no tombs were found inside the actual bins or niches. Moreover, the shape and volume of these features makes them inadequate to contain human bodies (Machicado 2009). Finally, these structures could have also been used to store agricultural surplus and any other significant items and tribute or even hold captives, underscoring the importance that taxation and coercion had in the economic and social reproduction for the Middle Formative Period communities.

Interestingly enough, well-preserved domestic houses associated with unambiguously domestic activities have been notoriously difficult to document at Chiripa and other contemporary sites (Hastorf 2017). Various factors contribute to obscuring the household evidence at Chiripa, including the absence of clear domestic vs. ritual contexts, and taphonomic factors affecting the site's conservation, most likely due to the intensive work by the hacienda phase of occupation. Some of these problems will be eventually overcome by carrying out additional excavations and improving the methodological approaches involved in studying the recovered cultural materials contexts.

Chongoni Rock Art Area

Benjamin Smith
Centre for Rock Art Research and Management, University of Western Australia, Perth, WA, Australia
Rock Art Research Institute, University of the Witwatersrand, Johannesburg, South Africa

Introduction

The Chongoni Rock Art Area was declared a UNESCO World Heritage Site in 2006. The area lies at the southernmost tip of Malaŵi's central plain, an area also known as the Ngoni Highlands. It contains 127 declared rock painting sites, about one site per km^2, making it one of the richest concentrations of rock art in Central Africa. The Highlands are scattered with hills, many having gneiss rock outcrops with natural shelters and overhangs as well as large boulders with protected surfaces. It is on these rocks that the painting sites are found (Figs. 1, 2, 3, 4, and 5).

Key Issues/Current Debates/Future Directions/Examples

Early Studies

The existence of paintings in this area has been known since the 1920s when Margaret Metcalfe (1956) reported sites on Mphunzi, Chigwenembe, and Mlanda mountains. Further details were reported by Desmond Clark in 1959 as part of his general synthesis of Zambian and Malaŵian rock art. In 1978 N. E. Lindgren and Matthew Schoffeleers published an inventory of 61 rock art sites, the total then known in Malaŵi. Of these sites, 35 lay within the Chongoni Rock Art Area. This brought about a broad recognition that Chongoni was the most important rock art region within Malaŵi. Lindgren and Schoffeleers set out a basic sequence for the art, dividing it into an earlier phase of geometric designs made by hunter-gatherers and a later phase of white finger paintings made by Chewa-speaking farmers. Emmanuel Anati worked in the area in 1986, evaluating the area on behalf of UNESCO for potential World Heritage Site listing. As part of this work, an updated inventory of known rock art sites was produced, and a substantial number of sites were visited. This inventory listed 117 known painting sites, 61 of which were within the Chongoni Rock Art Area. Yusuf Juwayeyi subsequently published more detailed information on a selection of sites and helped to confirm the stylistic sequence (Juwayeyi and Phiri 1992).

The Chongoni Rock Art Area was comprehensively surveyed in 1995 as part of a doctoral research project by Benjamin Smith. It was at this time that the total number of sites in the area was raised to 127, as listed in the UNESCO nomination. Some areas on the larger mountains are densely vegetated and proved hard to survey, so the actual number of rock art sites in the area could be as many as 150. Smith confirmed the findings of early researchers that the art separated into distinctive hunter-gatherer and farmer traditions (Smith 1997). He identified four traditions of rock art from these two periods (Smith 1997, 2005a, b, 2006): the red animal tradition, red geometric tradition, white spread-eagled tradition, and white zoomorphic tradition. The exact chronology of each tradition remains unknown, but their approximate age ranges can be determined from their cultural associations. Hunter-gatherers survived in this part of Malaŵi into the 1800s (Crader 1984), and it seems likely that the hunter-gatherer traditions continued up until this time. The cool, misty climate of the area is not conducive to long-term rock art preservation, and so while rock art has undoubtedly been painted in Chongoni over many millennia, most of the surviving art will be

Chongoni Rock Art Area, Fig. 1 View of Mphunzi mountain, one of the major public rock art areas within Chongoni Rock Art World Heritage Site

Chongoni Rock Art Area, Fig. 2 Red geometric tradition art: made by hunter-gatherers; note the fine *white dots* over the *red finger lines*

centuries rather than millennia old. The farmer rock art is linked by its distribution and ritual associations to Chewa-speaking groups who have only inhabited this area during the last 1000 years. The making of farmer rock art continued as recently as the 1950s (Zubieta 2006).

Current Understandings of Chongoni Rock Art

The hunter-gatherer art of this area is dominated by finger-painted geometric designs typical of the red geometric tradition (Smith 1997). Geometric tradition art was originally termed "schematic art" by Desmond Clark, and it is spread across most of Central Africa. Typical designs include concentric circles, rayed circles, sausage shapes, and internally linear divided stretched circle forms. These designs are almost always in red, and where well preserved, there is sometimes a white fill and/or white microdots between and over the red lines. Alongside these geometric tradition images is a small scatter of sites with finger dots and highly styled animal paintings, usually quadrupeds with vastly inflated bellies. The animal tradition images are generally found separated from the geometric art, either in neighboring sites or in separated parts of the same site. Within Central Africa there is a ratio of about ten geometric

Chongoni Rock Art Area, Fig. 3 White zoomorphic tradition art: made as part of Nyau secret society rituals by Chewa language speakers

Chongoni Rock Art Area, Fig. 4 White spread-eagled tradition images from Chentcherere 2 rock-shelter. This image was taken in the early 1990s before a series of tragic graffiti incidents

tradition sites for each animal tradition site, but in Chongoni the proportion of animal sites is even lower. The existence of two hunter-gatherer rock art traditions is explained in terms of a gender division, with the animal tradition being the art of men and the geometric tradition being the art of women (Smith 1997).

The former hunter-gatherers of Chongoni are remembered in a range of historically recorded oral traditions by the names BaTwa and Akafula (Rangeley 1963). While there are many traditions of their coming into conflict with farmer groups, archaeological evidence from Chongoni also points to localized symbiotic relationships with farmers (Crader 1984). The Malawian BaTwa are argued to have been closely related to modern-day Pygmy groups in terms of their culture and traditions (Smith 2005b, 2006; and see Namono 2010). Studies that have interpreted this art in terms of ongoing intangible heritage values associated with the sites combined with the application of Pygmy ethnographies have suggested that, while the ritual context and production of each of the two art traditions was separated, the symbolism underlying both traditions revolves around rainmaking, fertility, and social

Chongoni Rock Art Area, Fig. 5 Red animal tradition images from Chentcherere 1 rock-shelter

well-being (Prins and Hall 1994; Smith 1997, 2005b; Namono 2011, 2012).

The two more recent farmer traditions are of special importance because they comprise of one of the major concentrations of farmer rock art in sub-Saharan Africa. These traditions only occur in Chongoni and a small section of adjoining parts of Mozambique and Zambia. The farmer arts, as typical of all sub-Saharan African farmer arts, are finger painted and dominantly in white. The white spread-eagled tradition has been linked to a Chewa ritual ceremony called *chinamwali* (Smith 1997, 2005a; Zubieta 2006). *Chinamwali* is a girls' group initiation ceremony held at puberty. The art played a mnemonic role in the teaching of the young girl initiates (Smith 2005a; Zubieta 2012). While the art is no longer made today, some of its symbolism is still understood and still utilized, away from the rock-shelters, by women in modern-day ceremonies (Zubieta 2006, 2012). The other farmer rock art tradition, the white zoomorphic tradition, depicts spirit characters from the Chewamen's secret society: *Nyau* (Lindgren and Schoffeleers 1978; Smith 1997, 2005a). *Nyau* art was made during the time that the society was suppressed during the Ngoni wars, the early missions, and the colonial government (Smith 2001). The art served to train *Nyau* initiates in the secret *Nyau* terms and in the meanings of the large *Nyau* spirit characters that dance at almost all major Chewa social occasions. Today the art is no longer made; indeed, it is no longer needed because the suppression of *Nyau* has ended, and so *Nyau* teaching now happens in its original context (usually the graveyard).

Current Management of Chongoni

The Chongoni World Heritage Site is managed by the Malawian National Department of Antiquities. Many of the sites are within the Chongoni Forest Reserve, and so they also enjoy protection from forestry staff. Some sites are preserved in their original forest setting although much of the area is now under nonindigenous commercial pine plantation. A rock art tourism welcome center is located near Chentcherere hill. This center houses displays and offices for dedicated Antiquities management staff. The major sites open to the public include Chentcherere (excavated by Desmond Clark), Nthulu, Mphunzi, and Namzeze. In the absence of on-site management until 2013, there have been serious conservation problems, with dozens of sites severely damaged by fires and graffiti during the 2000s. In 2012, a US-based professional conservator, Claire Dean, worked at the major public sites removing graffiti. Chentcherere was returned to something close to its original glory. It is hoped that the new government management framework for the area will be able to ensure that the sites are more actively protected and conserved in the decades to come.

Christian Archaeology in Spain

Jordina Sales-Carbonell
Institut de Recerques en Cultures Medievals, Universitat de Barcelona, Barcelona, Spain

Introduction

As in much of the late Roman Empire, we may consider the search for holy bodies (*inventiones*) as a sort of Prehistory of Hispanic Christian Archaeology. Between the years 380 and 392, for instance, Asturius, Bishop of Toledo, led the *inventio* of the saintly corpses of Justus and Pastor in *Complutum* (Alcalá de Henares); around the year 619 Agapius of Córdoba successfully recovered the body of Saint Zoilus. Such primitive *inventiones* led to the construction, or else reconsecration, of a number of basilicas in which these bodies were guarded or rehoused – which in turn generated a range of new structures to be studied by Christian Archaeology at a later date. In the northern Iberian Peninsula, and also in other areas under Saracen control, a number of saintly graves were uncovered after the Muslim occupation. These efforts were driven by local and Carolingian political and religious elites who, in the midst of the *Reconquista*, wished to secure their legitimacy in newly conquered territories. Three well-known examples are those of Saint Eulalia in Barcelona (878), Saint James the Great in Santiago de Compostela (825–829), and Saint Vincent in Valencia (855). The practice continued throughout the Middle Ages – a period of considerable growth in ecclesiastic initiatives tasked with locating new relics or broader sites of martyrdom, now solely for religious purposes.

Definition

Either as a key topic or a branch of the historical science, Christian Archaeology focuses its attention on the identification of the material manifestations of Christianity of the first centuries, especially those of the Roman Empire and Late Antiquity. In Hispania (current Spain and Portugal), the time frame of its range of study ends with the Muslim occupation (711 AD).

Key Issues/Current Debates/Future Directions/Examples

Fifteenth-century Italy witnessed the birth of a movement tasked with reconnecting with its classical past. By the sixteenth century it had spread to Spain, with sources mentioning early attempts at establishing a tentative archaeological science. As far as the Christian past is concerned, a number of excavations were undertaken in Alcázar de Arjona (Jaén) in search of third-century martyrs, and in the church of Saints Justus and Pastor in Barcelona (1590), where attempts were made to find Pacianus, one of their earliest known bishops. By the seventeenth century, bones found during the excavation of the Baeza wall were readily attributed to Roman-era martyrs. The discovery and excavation of the great basilica of *Segobriga* (Cuenca) during the eighteenth century is the first such news concerning the identification of a Late Antiquity basilica in Hispania (Capistrano de Moya 1792).

The monumental *España Sagrada* of father Enrique Flórez, published after 1747, is the starting point of scientific works in Christian archaeology in Spain. Still widely consulted and cited, it gathers all known facts at the time concerning not only ecclesiastic history but also Christian monuments in the Iberian Peninsula. In many cases, it is the sole witness to churches and buildings long disappeared. The discovery in 1858 of the Guarrazar treasure in Toledo (a range of crosses and golden votive crowns with encrusted jewels) led to yet another early location of Late Antiquity religious architecture in the Iberian Peninsula (Ríos Serrano 1861). Another such ecclesiastical treasure from Visigothic times was discovered, out of context, in Torredonjimeno (Jaen) in 1926. In the nineteenth century, the work of J. de Manjarrés (1867) is particularly noteworthy as the first Spanish lay author to deal in a broad manner with Christian archaeology, heavily inspired by French handbooks that flourished at the time.

In the twentieth century, J. Gudiol i Cunill published *Nocions d'arqueologia sagrada catalana* (1902), while J. Puig i Cadafalch of the Institut d'Estudis Catalans began a systematic excavation of a number of Hispanic churches and Paleochristian archaeological sites (Puig i Cadafalch 1961). In the years prior to the Civil War (1936–1939) and the early postwar years, the so-called "early core of a Christian archaeological school in Catalonia" (and indeed for the rest of Spain) began to take shape. Soon afterward, a towering figure in Spanish Christian archaeology arises: Pere de Palol i Salellas (1923–2005), who pioneered a truly modern, scientific, and systematic approach to the archaeology of the Hispanic Christian world of the pre-Middle Ages. His efforts were made possible by his chair in Christian Archaeology at the Universitat de Barcelona, the only such position in Spain which is currently headed by J.M. Gurt. Palol's works are substantial, but his *Arqueología cristiana de la España romana -siglos IV al VI-* (1967) is the definitive starting point for the consolidation of this science in the Iberian Peninsula. In 1964, Palol started the *Reuniones de Arqueología Cristiana Hispánica*, a fundamental meeting place in which to share news and summaries of Christian archaeology in Spain and Portugal. Its seventh edition will take place in 2018 (Fig. 1).

Just as Palol and his disciples undertook their enormous amount of excavation and investigation, the German Archaeological Institute of Madrid, headed by T. Hauschild, H. Schlunk, and T. Ulbert, developed a far-reaching research program that led to the volume *Die Denkmaler der frühchristlichen und westgotischen Zeit* (1978). A. Arbeiter has taken over this project and is currently updating the volume. After the

Christian Archaeology in Spain, Fig. 1 The pioneers of Christian Archaeology in Spain: Josep Gudiol i Cunill, Josep Puig i Cadafalch, and Pere de Palol i Salelles. (From Buenacasa Pérez and Sales-Carbonell 2015, p. 102)

publication of a critical and essential synthesis on architecture and liturgy (Godoy Fernández 1995) and the recent appearance of a few regional inventories of Christian archaeology (e.g., Palol i Salellas, ed. 1999; Mateos Cruz and Caballero Zoreda 2003; Sastre de Diego 2011; Sales-Carbonell 2012; Sánchez-Pardo 2012; Sánchez Ramos et al. 2015), a comprehensive inventory of Late Antiquity and Early Medieval Christian architecture is being coordinated by G. Ripoll as part of the international project *Corpus Architecturae Religiosae Europae (saec. IV–X)* directed by M. Jurkovic and G.P. Brogiolo.

In the meantime, the basics of architectural archaeology applied to Paleochristian monuments have been established and developed by the works of L. Caballero-Zoreda, beginning in the last two decades of the twentieth and the early twenty-first century. Christian Archaeology in Portugal, which is part and parcel of the Hispanic frame, has emerged during the second half of the twentieth century following the summary work of F. De Almeida (1962) and has led to underground investigations in Mértola, Troya, Viseu, and Dume.

In an urban context, the increasingly well-known Christian skyline from the Late Antiquity era stands as some of the most emblematic archaeological traces of ancient Christian Hispania. Their overall span is considerable, as is the number of publications concerning archaeological activities and investigations undertaken in the last few decades in episcopal cities such as Barcelona, Mérida, Valencia, Córdoba, or Empúries. In Tarragona, the extensive Paleochristian necropolis has been subjected to a number of revisions. In recent years, an entire floor of a new basilica has been excavated (the northern or "Septentrional Basilica") and the amphitheater, with its own sixth-century basilica erected inside the arena to commemorate the martyrdom of bishop Fructuosus, stands as a towering example of a Christianized Roman spectacle building. In Córdoba, the so-called palacio de Cercadilla corresponds to a colossal structure from the tetrarchic era which in the ensuing centuries adapted its spaces to host Christian constructions. In minor episcopal sees, such as *Ilici* (La Alcudia de Elche), a so-called synagogue-basilica was discovered over a century ago – an interesting structure

which, not without some controversy, has been interpreted as a synagogue at some point turned into a place of Christian worship. In Portugal, the Paleochristian basilica of Mértola is home to a series of underground tombs which contained in situ a significant collection of explicit funerary epigraphs, including details of those buried there and their links with the local church.

In Dume, the large basilica of the former episcopal see has also been identified: it arose from its namesake monastery founded by Martin of Braga in the mid-sixth century. Such vestiges of ancient episcopal sees have been unearthed within a current urban landscape, for these are towns and cities that have survived and evolved into our modern times. This is not the case for towns like El Tolmo de Minateda (the episcopal see of *Elo*, Albacete), which was already abandoned in the Middle Ages; the same can be said for *Recopolis* (Zorita de los Canes, Guadalajara), which was founded by the Visigothic king Reccared I. Both locations were rediscovered only a few decades ago.

At a rural level, a number of basilicas are noteworthy, such as those in El Gatillo de Arriba, Santa Lucía del Trampal, Alconétar (Cáceres), El Germo (Córdoba), Valdecebar, Casa Herrera, San Pedro de Alcántara (Badajoz), Vega del Mar (Málaga), Cabezo de Griego (Cuenca), Santa Comba de Bande (Orense), Quintanilla de las Viñas (Burgos), San Juan de Baños (Palencia), San Pedro de la Nave (Zamora), Marialba (León), Villa Fortunatus (Huesca), Santa Margarida de Martorell, Sant Mena (Barcelona), El Bovalar (Lleida), and Torre de Palma (Monforte, Portugal). Many of these rural churches, some of them born out of prior Roman *villae*, would in time develop into parishes which are currently densely populated urban centers, leaving little trace of their original rustic character. On the other hand, an increasing number of Late Antiquity *villae* with apsidal chambers is being linked to the spread of Christianity in the countryside, despite a lack of archaeological data which could properly contextualize this process and provide a clear outline of its stages – a process, one should add, that likely varied from one region to the other. Also worth mentioning is the outstanding archaeological site and monument of Centcelles: a spectacular Christian mausoleum from the fourth century linked to the Constantinian dynasty and which preserves its entire structure along with parts of the dome's mosaic.

In recent decades, the archaeological context of the legendary tomb of the apostle James (in Santiago de Compostela, Galicia) along with its relation to written sources from the late fourth century have given rise to the theory that it actually belongs to bishop Priscillian of Avila, the real owner of this holy tomb. If we include the Balearic Islands, one must mention the rural sites headed by the basilicas of Son Peretó, Son Fadrinet, Sa Carroja (Mallorca), Cap des Port, Es Fornás de Torelló, Son Bou, Illa del Rei (Menorca), and the large place of worship in Sanisera (Sa Nitja, Menorca), consisting of at least two basilicas, seven necropolis, as well as both urban and productive areas along with necessary facilities to accommodate the needs of housing and economic output.

One of the main problems of Christian archaeology in Spain remains the location (or, more precisely, the archaeological identification) of its earliest monasteries, from the fifth to seventh centuries. After the Muslim invasion, traces of monasteries are easily identifiable, if anything because of the significant amount of written sources that point to their exact location, as well as the increasing use of recognizable architectural models. This is not the case for Late Antiquity, with a dire lack of written sources and a set of archaeological remains which can be easily confused with lay villages and other such settlements. So much was said in 2006, when it was stated that "it is impossible or it seems impossible to find any trace of the earliest monasteries in Hispania" (Caballero Zoreda 2006: 121). Nevertheless, a number of archaeological remains which can be linked to monasteries have been uncovered in sites in Santa María de Melque (Toledo), El Monastil (Alicante), Ercávica (Cuenca), Els Altimiris (Lleida), Islote de Cabrera (Baleares), or Sanitja (Menorca). Likewise, the site of El Bovalar (Lleida) has been reinterpreted as a monastery which specialized in parchment production – excavated in the 1980s and initially classified as

a lay village with a basilica from the sixth to seventh century, there remained the thorny issue of its significant liturgical furniture. A rich sixth-century monastery was sadly destroyed in the 1960s construction frenzy in La Punta de l'Illa de Cullera, in the Valencian coast – a monastery likely to have been founded by the bishop Justinian of Valencia within a fortified island, according to an inscription on his tomb. The aforementioned place of worship in Sanisera (Menorca) was likely been run by a monastic community, and as such, parts of its "urban zone" would be better understood within the context of a monastery.

Christian Topographies During Late Antiquity and the Early Middle Ages

Gabriele Castiglia
Pontificio Istituto di Archeologia Cristiana (PIAC) – ROMA, Rome, Italy

Christian topography represents a branch of Late Antiquity and Early Medieval's archaeology. Its main objective is the study and comprehension of the material and monumental dynamics of affirmation of Christianity in urban, suburban, and rural contexts. More precisely, Christian topography studies – through a transversal approach of the written, epigraphic, archaeological, and architectonical sources – dynamics and modalities of the development of the network of Christian buildings' structures, which became characteristic of the urban skyline and of the Mediterranean countryside and, more globally, of the Roman world (often way beyond the limits of Late Antiquity) since the fourth–fifth century A.D.

Now more than ever, Christian topography has to be considered as a global discipline.

Because of the reduction of Christian archaeology's chairs in universities, especially within those European countries where its *status* had always been most developed (such as Italy, France, Germany or Spain), it is fundamental to revalue a methodology that has proven itself essential in order to understand the complex stages that lead from the classical *civitas* to the early medieval urbanism and to the transformation of the rural landscapes, with a form of global

archaeology, precursor for the understanding of the urban, rural, and social dynamics of Late Antiquity. As recently stated by N. Gauthier, "*la lente conquête de l'espace urbain par les édifices chrétiens est la vraie révolution urbaine de ces siècles de transition entre Antiquité et Moyen Age"* (Gauthier 2014) .

The 16 volumes of the *Topographie chrétienne des cités de la Gaule des origines au milieu du VIII*^{ème} *siècle*, which have been completed a few years ago (Prévot 2014), can be considered the first milestone of "modern" Christian topography. It is also worth mentioning *Le développement urbain en Provence, de l'époque romaine au XIV*^{ème} *siècle,* the innovative volume written by Paul-Albert Février in 1964a. This method was developed at the University of La Sorbonne in Paris in the 1960s thanks to scholars like Noël Duval, Paul-Albert Février, and Charles Pietri. The method was characterized by a rigorous approach since the start. In fact, it required to fill up a complete and concise dossier about the cities of *Galliae*, starting from the classical era, that had to analyze the topographic evolutions resulted from the impact of Christianity in a long term perspective. No hierarchical preeminence was given to the available sources, such as horizontal and vertical stratigraphies, epigraphy, history of art, written sources, burial studies. The innovative aspect of this methodology is that "while Christian archaeology has limited its analysis to issues related to Christian worship spaces and to the most eye-catching aspects of private and public Christianity, the discipline has been able to embrace data from all historical periods linked to the birth and development of the *civitas christiana* thanks to Christian topography" (Pergola 2003, p. 342; for recent methodological updates see Pergola 2014 and Castiglia in press). According to this global approach, a research of Christian topography has to refer, at first, to the historical origins of dioceses.

It is a fundamental stage in which the researcher must apply philological rigor, since it is often possible to come across forgeries. In fact, especially during (and immediately after) the Middle Age, numerous sources intentionally used forgery to attribute "apostolic" origins to dioceses in order to establish the authority of a city (or a territory) over another. As a consequence, historical documents such as, *in primis*, the acts of councils allow us to go back to official statements of bishops from various areas of the ancient world with a philologically orthodox methodology. An essential point of reference that collects all the councils is represented by the monumental work of J.D. Mansi, which was published in several volumes in the eighth century (*Sacrorum Conciliorum nova et amplissima collectio*, Firenze-Venezia 1759–1798). It is worth mentioning other two prosopographical works (mainly relevant to the Italian panorama): *Le diocesi d'Italia, dalle origini al principio del secolo VII*, published by F. Lanzoni in Faenza in 1927 and the *Prosopographie Chrétienne du Bas-Empire 1–2. Prosopographie de l'Italie Chrétienne (313–604)*, published by Charles and Luce Pietri in Rome, in 1999. The first work, published in 1927, despite being dated, still represents a very important critical instrument to start from, while the second one is a very rich source with plenty of references to the original sources.

The "new phenomena" of church architecture started to impose itself from the Constantinian age, except for the catacombs that were present in Rome and Carthage from the end of the second century A.D. – beginning of the third century A.D. (Fiocchi Nicolai 2001; Pergola 1997). Church architecture first appeared in suburban contexts, such as in the *extra moenia* perimeter of the Constantinian Rome, where several martyrial and funerary churches were built together with catacombs (Fiocchi Nicolai 2015, 2016; Spera 2014) (Fig. 1). On the other hand, the monumental affirmation of Christianity *intra muros* started in the Theodosian age: archaeological evidence reveals the incidence of Christian topography over the patterns of settlement from the end of the fourth century A.D. The development of this tendency reached the peak from the end of the fourth century A.D., till the end of the sixth century A.D. (Cantino Wataghin et al. 1996). In this complex panorama, the *ecclesiae episcopales* (the term "cathedral" was introduced in the Middle Ages) represent a symbol of the new Christian topography. They are, evidently, the most important and clear expression of the new

Christian Topographies During Late Antiquity and the Early Middle Ages, Fig. 1 The suburban churches in 4th century Rome, before year 358 AD (after Fiocchi Nicolai 2016)

actores of power within the late-antique towns, evidently the bishops. The *episcopi*, in fact, were not only the emissaries of the word of God on Earth but gained a growing control over the political, economic, and topographical issues of towns and their territories during Late Antiquity and the Early Middle Ages. We have many examples, but one of the most notorious is with no doubt St. Ambrose (337–397 AD) who, as a bishop of Milan, fully re-shaped the topography and image of the town in the late fourth century AD (see Lusuardi Siena et al. 2015 and relative bibliography); another important figure of "bishop-manager" has been that of *Sabinus* from Canosa, in southern Italy who, in the sixth century, not only gave a fundamental contribution in the re-launch of the town, by promoting important buildings and activities, but was also a real businessman, producing tiles with his own monogram (Volpe 2007, 2008).

Compared to the criteria of centrality of the *civitates* of the classical period, the *ecclesiae episcopales* were built in marginal areas within the city (Testini et al. 1989; Cantino Wataghin

2015). There are several exceptions of course, Pisa among the others. In Pisa, evidence of the baptistery of the first *ecclesia episcopalis* dates back to the sixth century (Pani Ermini and Stiaffini 1985) and it was apparently located in the area where we can find the *Campo dei Miracoli* today (see Alberti and Paribeni 2011), but due to limited information about the city in the Roman period and Late Antiquity, we are not able to confirm its precise location. In *Cornus* the *ecclesia episcopalis* was built in a funerary area, but its location is still debated, especially the relationship between the settlements of the Late Antiquity and the Christian topography, such as the dichotomy of the two poles of *Senafer-Cornus* (see Pergola et al. 2010, pp. 393–402). *Concordia* is also an important case study, and its *Basilica Apostolorum* is considered the first *ecclesia episcopalis.* It was built just outside of the city's walls, close to one of the city's doors at east, commissioned by Cromazio di Aquileia at the end of the fourth century to guard the relics of the Apostles Andrea and Tommaso, Saint John the Baptist, Luca and Saint John the Evangelist (Bovini 1973). Christian urban topography presented a variety of religious buildings besides the *ecclesiae episcopales*. By the end of the sixth century A.D., almost all urban areas had religious buildings with several functions. Ph. Pergola has recently highlighted how the systematic Christianization of all classes was completed by the late fifth century. The author also points out how correspondent to this phenomenon was the construction of monumental Christian complexes in all residential and public areas, along with the first cases of reuse and abandonment of structures that had lost their original functions (Pergola 2003, pp. 151–152). By the half of the fifth century A.D., urban chapels called *tituli* proliferated in Rome (Spera 2014; Pietri 1976; Pietri 1989; Guidobaldi 2000). The *tituli* were ceremonial places of worship located within not religious buildings, they were self-financed structures, and they probably even contributed to finance the hierarchical summit of the church (Guidobaldi 2000, pp. 124–125) (Fig. 2). The definition of Christian topography is not limited to the *intra moenia* spaces, but it also includes the *suburbia* as the main location of burial areas before the inclusion of graveyards within the urban spaces in the sixth century A.D. (see *infra*). The most important funeral areas were catacombs complexes and basilicas. Catacombs often became a crucial meeting point for Christian communities before the Constantinian turn; they were in fact not just funeral sites, but also devotional places and destinations of pilgrimages. The suburban basilicas can often be considered as cemeteries as, for example, the ambulatory churches of the Roman *suburbium* (all dated to the Constantinian period and also known as "*circiformi*"), which were often linked to important martyrs. The suburban churches became polyfunctional places where funerals and devotional activities took place according to the weekly canonical liturgy. The martyrs and their memories played a fundamental role, as exemplified by the case of the suburb of *Arles*-Arelate in the south of France: in this area two different funeral areas developed around the cult of St. Genesio, one of them being the site of the martyrdom of the Saint and the other its sepulcher (this is where the *Basilica Beati Genesii* is attested in the middle of the fifth century A.D.) (see Heijmans 2014).

The progressive introduction of funerary areas within the walls of the cities is considered an element of extraordinary influence over the morphogenetic capacity of urban areas: several interpretations of this phenomenon have been given by researchers, often linked to a sign of decadence of the sense of *decorum* of the city and of a widespread crisis. The complexity of this issue has been discussed by U.M. Fasola e V. Fiocchi Nicolai at the 11th International Congress of Archaeology in 1986, where their report and the rich debate that followed are still a fundamental reference point regarding the Italian and European context (Fasola, Fiocchi Nicolai 1989). This stimulating contribution was followed by an important study day organized as part of the *Seminars of Christian Archaeology* in Rome (12th March 1987) (Pergola 1987). An updated summary of the situation in the peninsula was presented at the conference *Sepolture tra IV e VIII secolo,* (Burials between the fourth and the eighth century A.D.) (Brogiolo and Cantino Wataghin 1998).

Christian Topographies During Late Antiquity and the Early Middle Ages, Fig. 2 The Roman *tituli* (by Stefano del Lungo)

C

The issue had also been discussed by V. Fiocchi Nicolai during the 50th study week at the *Centro Italiano di Studi sull'Alto Medioevo* (CISAM) in Spoleto in 2002; modalities and time span of the appropriation of urban spaces by burials were part of the debate. One of the most critical issues detected by V. Fiocchi Nicolai was the precise chronological definition of the initial stages of the phenomenon, an issue that it is still debated nowadays, even though the data coming from various areas of the *Orbis christianus antiques* warn not to fall into generalizations. For what concerns North Africa, P. A. Février has proven how the relocation of urban burials was already happening there in the second half of the fourth century A.D. (Février 1964b), as attested by the case of *Sétif* (Février 1964b, 1965). The practice continued in the fifth century A.D., as proven by the burial of Bishop *Jucundus*, found in an appendix of Sbeitla-*Sufetula*'s "*Basilica I*" and dated around the third-fourth decade of the fifth century A.D. (Duval 1971) (Fig. 3).

Generally speaking, the African data do not seem to mirror the situation of other areas, such as Italy and the East, again with some exceptions. V. Fiocchi Nicolai points out evidence of the practice in Constantinople in 381 A.D.: Theodosius, in fact, imposed fines to whom who would bury *intra moenia*, indirectly attesting the presence of burials within the walls of the city at the end of the fourth century A.D. (Fiocchi Nicolai 2003, pp. 948–949; *Codex Theodosianus*, IX, 17, 6 = Th. Mommsen (ed.), *Theodosiani libri XVI* cum *constitutionibus sirmondianis et leges novellae ad Theodosianum pertinentes*, I/2, p. 495). Despite the similar chronological span, we can easily detect a difference between the practice in North Africa and the one Constantinople: in the first case we have an *episcopus'* burial within a church that proves the support of the religious authorities, while in Constantinople the introduction of a fine clearly attests the intention of the authorities to limit the tendency to move the burials within the walls of the city. The spreading of this practice has heterogeneous reasons, such as the desegregation of the urban walls, the urgency, the intention of a burial *ad sanctos* (Fiocchi Nicolai 2003, p. 951), but the most important and official role was played by the religious buildings where Christian ceremonies were celebrated, which constituted the vectors of urban and suburban transformations in Late Antiquity and Early Middle Age (Pani Ermini 1998; 2001).

In the Early Middle Ages, urban spaces were characterized more and more by an emerging Christian topography, a phenomenon that in many cities (such as Rome) had already begun in the Late Antiquity. The coexistence of centers of ecclesiastical and temporal power is evident under the Kingdom of the Lombards (in Italy) and the Carolingian domain. In some of the most important European urban centers *curtes*, *palatia*, and mints replaced the spaces of classical *civitates*. Even when located in outlying areas, these structures became districts of power that went to complement the Episcopal centers.

We can find an example of the newborn tight connection between ecclesiastical and temporal power by analyzing the origins of the bishops of Lucca between the 8th and the ninth century A.D., being them all part of the local aristocracy, as brilliantly highlighted by A. Mailloux (Mailloux 1999). The ecclesiastic body acquired managerial responsibilities that previously belonged to state and temporal institutions: this extension of the Episcopal control over the civic jurisdiction has been recently well documented in Rome in the eighth century A.D. (Spera 2016).

In the same way, we find most notaries among the ecclesiastics, while the latter – bishops *in primis* – acquire public powers (Mailloux 1999, p. 710). The city of Pistoia exemplifies well these dynamics through its topography: the new road axis built during the Lombard era was symbolically called via *regis* and along this route we could find the *ecclesia episcopalis*, the *curtis*, the *Palatium*, and, probably, even a mint.

In rural areas, even more than within the cities, the spreading of Christianity and its characteristic topography followed a heterogeneous development, depending on the various geographical areas (Cantino Wataghin 2013a, b; Monfrin 2002). Despite being dated, a relevant contribution in this sense is still the lesson given by C. Violante at the seminar organized by CISAM in 1980 and published in 1982 (Violante 1082).

Christian Topographies During Late Antiquity and the Early Middle Ages, Fig. 3 Top: The topography of Sétif (after Février 1964b). Bottom: The Basilica I in Sbeitla (after Duval 1971)

During his lesson, the researcher provided a wide overview of the development of rural ecclesiastic infrastructures in the *post* Roman and Early Medieval countryside. His study was based almost exclusively on the exegesis of written sources and presented a few fundamental points. First, the necessity to leave behind the "principle of territoriality." In fact, in order to determine to what diocese a new oratory belonged to, people had to verify to whom the devotees referred to for the sacraments (Violante 1982, pp. 972–974). Second, with the gradual conversion of the Lombards to Christianity, the number of baptismal churches increased exponentially and developed into a structured network. Documents start to report the term *plebs*-, referring to the relevant territory of a baptismal church together with the *ecclesia* itself, which had a baptistery for the pastoral care of the population (Violante 1982, pp. 1015–1016). Another essential role of the *plebes* was of being in charge of collecting the *decimae* (tithes). This was a Carolingian institution that contributed to reinforce the rural ecclesiastic network as the center of the economic and fiscal life of the Early Medieval countryside (Violante 1982, pp. 1072–1084).

C. Violante's work is still relevant nowadays and his conclusions are partially confirmed by archaeological data, even if we must take into account specific geographical differentiations. The case of Tuscany, for instance, well highlights how a non-structured Christian topography was already present during Late Antiquity and how it became more systematized and widespread from the eighth century A.D. onwards, when the previous system fell apart (regarding the gradual introduction of the parish system in the countryside see Pergola 1999; *L'edificio battesimale in Italia*; Delaplace 2005; regarding the case of Tuscany see Castiglia 2017 and Castiglia 2018).

One of the most important and debated topics for the Late Antiquity refers to the occupation of premises (villas and "secondary settlements" *in primis*) located in rural areas in the Roman period by churches. It is not clear in fact if there was continuity or not between the structures: were the churches created within the inhabited villas or they went to occupy destructured or even abandoned buildings? What was the role of the lay aristocracies and of the bishops? It is very hard to give a clear answer to these questions since we rarely have at our disposal articulate stratigraphic sequences that allow us to ponder these phenomena in their entirety. There are two opposite sides of the debate. A. Chavarría Arnau depicts a scenario where the spreading of the rural ecclesiastic network would have been managed since the beginning by the ecclesiastic authorities in close connection with the evangelization process of the urban areas (Chavarría Arnau 2010a, b). On the other hand, K. Bowes claims that lay *élites* only had been in charge of the rootedness of Christianity in the countryside through material structures with no intervention from church authorities nor from their delegates (Bowes 2008). When researching the chronology of the Christianization of "secondary settlements," it is also complicated to find clear patterns. Despite the peculiarities of every single case, an important role has been played by the *mansiones*, probably thanks to their proximity to the major traffic routes of the *cursus publicus* (regarding the Christianization of the "secondary settlements" see Cantino Wataghin et al. 2007; regarding the relationship between Christian buildings and *mansiones*, see Corsi 2000, 2016).

Private intervention does not seem to have played a role in the evangelization, but it has been functional to the material spread of the ecclesiastic network. As pointed out by C. Violante, this aspect had created frictions: the popes in fact were concerned (Gelasio, Pelagio, Gregorio Magno) about the autonomous initiatives of the *élites* (Violante 1982, p. 1012). From the letters of the popes, we can infer the existence of cases in which private citizens would build baptisteries within their estates without the *imprimatur* of the *episcopi* or at times, just with their initial approval. At the same time, those letters indicate how the delocalization of the baptismal rite was already happening at this stage, even if not in a systematic way, an aspect that had been highlighted by V. Fiocchi Nicolai and S. Gelichi at the 8th National Congress of Christian Archaeology (Fiocchi Nicolai and Gelichi 2001, pp. 304–307). The two researchers quote a particularly interesting passage from Saint

Girolamo, *Dialogo con i Luciferiani* (ca. 382 d.C.) (Hier., *C. Lucif.*, 9, coll. 164–165). In this passage, the Father of the Church referred to the "*ecclesiarum consuetudeo*" to have the people who lived far away *a maioribus urbibus in villulis, aut in castellis aut in remotioribus locis* baptized by presbyters and deacons (*per presbyteros et diaconos*); the bishop was still in charge of the *consignatio* of the neophytes that was given to the worshippers during a later pastoral visit in those places (Fiocchi Nicolai and Gelichi 2001, p. 305). The mentioning of an *ecclesiarum consuetudo* (complied or not) leads us to the conclusion that giving the baptism in rural churches was initially under the direct pertinence of the ecclesiastic hierarchies and that as such it had to be recognized by the county and, as mentioned by V. Saxer, we should also be aware of the various regional contexts especially at these stages (Saxer 1988, p. 107).

Specific characteristics at a regional and microregional level represent one of the most relevant aspects to consider when it comes to the means by which Christianity materially spread into the rural areas, especially in Late Antiquity and Early Middle Ages. In the urban areas, we can draw some generalizations of the development of a Christian topography while the countryside presents a more heterogeneous progress.

We can observe an example of macroregional diversification by comparing the Italian and the Gallic countrysides: in fact, the two territories present different evolutions of the formation of the ecclesiastic network from Late Antiquity. In 1982, C. Violante stated that in Late Antiquity the pastoral care of the faithful was not influenced by principles of territoriality (Violante 1982, pp. 972–973; Cantino Wataghin 2013b). The same thesis was supported also by G. Fournier who claimed that the rural ecclesiastic network adjusted itself into previous infrastructures (Fournier 1982): the scholar also defined those churches as "*centres liturgiques de caractère public"* (Fournier 1982, p. 499) since their area of influence did not seem clearly defined. As a consequence, it seems too early to talk about "parish" for what seemed more the emergence of a "pre-parish" (Pergola 1999; Delaplace 2002, p. 12). While analyzing this phenomenon, as mentioned before, it is important to take into account specific regional features: on this matter in 1999 Ph. Pergola stated that "there doesn't seem to be any rule [. . .] beyond the regional borders" (Pergola 1999, p. 634). A. Castagnetti is the author of one of the most influential studies about Italian rural churches. In 1982, the researcher stated several times that the transition from the Roman *pagus*, with its strong principle of territoriality, to the rural churches in Late Antiquity and in the Early Middle Ages, represented a breaking point characterized by discontinuities (Castagnetti 1982, pp. 25–27). Referring to the *lectio* of Violante, Castagnetti stated that regarding the administrative organization of *pagi*, the new term *paroecia* had no territorial value, but it indicated just a community of worshippers (Castagnetti 1982, p. 27). This statement has also been confirmed by a famous quote by Pope *Gelasius*: "*territorium etiam non facere diocesim*" (Thiel 1868, fr. 17, pp. 492–493). This quote has been included in a paper by M. Lauwers': according to this author the popes had replaced the concept of "territoriality of power" with the idea of "bonds of personal dependency" (Lauwers 2008, p. 30). On the other hand, L. Pietri highlights that this phenomena was not present at that time in *Gallia*. It seems in fact that on the other side of the Alps the situation was different since the pope did not apply the same level of authority and control over those territories and as a consequence the directives issued by Episcopal councils referred to pertinences specifically linked to the *territorium*, in order to solve the conflicts of the bishops over territorial jurisdiction (Pietri 2005, p. 237).

Ecclesiastic structures proliferated in the cities as well as in the countryside during the Early Middle Ages (especially in the late 8th and in the ninth century A.D.). During Lombard Era religious infrastructures where mainly in the cities, while starting from the Carolingian Era we assist to a trend reversal and the countryside witnesses the multiplication of new churches. This phenomenon is the result of the spreading of the economic and religious control from the cities to the rural areas: in the early Lombard Era (at least until the first decades

of the seventh century A.D.) in fact, the aristocracy lived mainly *intra moenia* while controlling productive activities in the countryside. Recent studies have confirmed how the Episcopal control over the rural areas grew stronger during the Carolingian Era, mainly in the ninth century A.D. (Bührer-Thierry 2007; Stoffella 2016, p. 101). M. Stoffella researched the strategies of control implemented at that time and stated: "*several strategies were implemented by the bishops to take control of power: their consecration, the pressure wielded by bishops on the founding families for their demise, the translation of relics, the strengthening of religious cults within those centres already widely under the control of the episcopal see in the localities through the rectors of the numerous baptismal churches*" (Stoffella 2016, p. 102; on the same topic see Stoffella 2008 and Stoffella 2011). Together with these religious practices, the spreading of an ecclesiastic network was strictly linked to the collection of tithes (*decimae*) (taxes paid by tenants in the rural areas, equal to one tenth of their income and to be paid to the church, which owned most of the lands at that time). The tithes were paid at rural baptismal churches as clearly stated in a *capitolatus* in 813 A.D.: *familiae vero ibi dent decimas suas ubi infantes eorum baptizantur, et ubi per totum anni circulum missas audiunt* (*MGH, Concilia Aevi Karolini*, p. 277). S. Wood defined the church at that time as a *proprietary church* (Wood 2006).

Dioceses in rural areas are also an interesting phenomenon that has been studied by researchers in the last 20 years (as a general reference see De Fino 2005, 2015; regarding the islands see Istria and Pergola 2009). According to the most recent studies, we can count around 30 rural dioceses mainly located in the center and in the south of the peninsula, while not many were present in the northern part (De Fino 2015) (Fig. 4).

All those dioceses seemed to have some common traits: they were all located by the main routes (roads and rivers *in primis*) and far away from the cities, they were located within administrative centers owned by the empire and they also had a limited lifespan (De Fino 2005, p. 699). A perfect example is San Giusto, a compound located in the plains of the Tavoliere delle Puglie, close to Lucera and to the area of *saltus Carminianensis*, as mentioned in the *Notitia Dignitatum Occidentis* (*Not. Dign.* XII-8). The *saltus Carminianensis* was an important center of imperial administration: it was in charge of the management of agricultural and pastoral activities in that territory and, thanks to its influence, a very important rural diocese started to grow in that area (De Fino 2005, p. 695). The site had been identified at the end of the Nineties by G. Volpe and his team, and they were conducting an archaeological survey close to Celone river where a dam was going to be built (Volpe 1998). The excavations revealed a large site that had been populated since the Republican Era, where a rural villa was built between the first and the second century A.D. During the fifth century A.D., a large basilica with a semicircular apse was built, with a vestibule, three naves, and a baptistery. The worship area (known as "Chiesa A") had a rich mosaic pavement that covered around 70% of the surface. A circular baptistery was located close to this structure and it was quite peculiar for a Christian complex of the fifth century, since it was very large (16 meters of diameter). A new basilica (known as "Chiesa B") was built in the sixth century a few meters west of the previous one: this basilica was mainly used for funerary purposes, as confirmed by the several burials that have been found disposed in parallel lines within its walls. According to G. Volpe, the compound of San Giusto, with its two large basilicas and the big baptistery, was the center of a rural diocese (sources from the Roman synods of 501 and 502 A.D. attested the presence of *Probus, episcopus ecclesiae Carminianensis* – J. D. Mansi 1759–1798, Vol. VIII, p. 308 and p. 317). To confirm his statement, researchers have found bricks, probably produced in loco, with the monogram of *Iohannis* (Volpe 2002), who was probably a local bishop, and this monogram symbolizes his responsibilities over production and productivity besides the *cura animarum* (Fig. 5).

In this part of the paper, I am going to present an urban case study. *Νέα Αγχίαλος*, in Greece, is an emblematic case of evolution of a Christian topography as transformative and innovative element in the development of a city in the Late Antiquity and High Middle Ages.

Christian Topographies During Late Antiquity and the Early Middle Ages, Fig. 4 The rural dioceses in the Italian Peninsula and in Corsica (after De Fino 2015)

Christian Topographies During Late Antiquity and the Early Middle Ages, Fig. 5 The site of San Giusto (after Volpe 1998)

Νέα Αγχίαλος, called *Θῆβαι Φθία* in the past (regarding the context see Sotiriou 1931; Pallas 1977; Karagiorgu 2001, 2013), took its name from a fairly recent event. In 1906, due to the Greek- Bulgarian conflict in the Ottoman Macedonia, Greek exiles moved to this area from *Αγχίαλος*, a small city by the Black Sea which is called *Pomorie* nowadays. The exiles once arrived there founded the "New Anchialos" on the site where the ancient center of *Πύρασος* once was. *Πύρασος* had also been mentioned in the Iliade (Omero, *Iliade*, B. 695) and by *Strabo*, who said that this center was once a port town and originally located 20 *stadia* from *Θῆβαι Φθία* (Στράβων, *geogr.*, IX, 435): the two settlements were unified around the fourth century B.C.

From a geographical point of view, the area where the exiles decided to settle is located in the south-eastern Tessaglia at the end of a large flat, not far from Mount *Όθρυς*: the acropolis was erected on a small hill facing the Pagasitic Gulf, a strategic location since it could control both the hinterland and the coast. *Θῆβαι Φθία* was located eighteen kilometers west of the important city of *Δημητριάδα* (founded in 293 B.C.) and a conflict soon emerged between the two centers. During the war, the Macedonian king, Philip V (238–179 B.C.) sided with *Δημητριάδα* and defeated *Θῆβαι Φθία*, so that the city started to slowly regain its strength around the first century B.C.

The walls of the ancient city (mentioned as one of the most important cities in *Tessaglia* in the *Συνέκδημος*, a geographical work of the sixth century A.D. by *Ἱεροκλῆς*) were mainly located around the acropolis and their irregular profile followed the valley towards west. The most ancient part was built in the fourth century B.C., at the time of the union of the two centers of *Θῆβαι Φθία* and *Πύρασος* and reinforced around the fourth–fifth century B.C. by adding several rectangular towers.

At the foot of the acropolis, there was the *forum*. Built in Late Antiquity, the *forum* was object of

several structural changes and it became a multi-functional area, mainly devoted to commercial activities (this is why it was also called "Market"). It had rooms to store food, kitchens, laundries and also hosted a production of ceramics and bricks, the latter with the words *ΕΚΚΛ(ησίας) Θ*Η*Β(ῶν)* written on; bricks marked with the same words were found in the "Basilica A" (see below). Within the walls, there was also large *thermae* that had been used from the fourth to the sixth century A.D., as confirmed by the style of the last mosaic pavements.

Thanks to a reference to *Κλεόνικος Θηβῶν* at the council of Nicea, we know about the presence of an *episcopus* in 325 A.D., so that we can trace the emergency of Christianity in the city. The most ancient church of *Θῆβαι* was erected in the south western corner of the city at the end of the fourth century A.D. Referring to its first phase, the basilica is known as "Basilica H": it was built on a preexisting structure whose walls and mosaic pavement suggest that it probably was originally a *domus;* in the second phase, in the fifth century A.D., it is called "Basilica G," and it grew towards east and a large apse was added. The third and last phase is dated to the sixth century A.D.: in this phase the basilica is known as "Basilica C" or *"Basilica of Bishop Peter."* At that time the basilica was further extended towards west: its large floor plan was divided in three naves and two colonnades, and it was 88,50 m long and 26,80 m wide (including the *atrium* and two narthexes); the church was also embellished by mosaic pavements, marble plates, and frescoes. This basilica has never been explicitly mentioned as *ecclesia episcopalis*, but besides its monumental size there are other elements that indicate its role such as the two baptisteries known as *Little baptistery* and *Big baptistery*: the first baptistery is characterized by its small size (2,10 m each side) and it is located in the Northern part of the basilica, close to the two narthexes.

The second baptistery, located in the southern part of the large basilica, represents one of the grandest examples of baptistery in Greece. The baptistery was surrounded by other rooms that appeared to be the residency of the bishop. Later interventions are dated to the sixth century A.D., such as the inscription with the name of Bishop Peter that gave the name to the basilica.

Another important structure in the city was the so-called "Basilica A" or "Basilica of San Demetrios." Similar to the previous one in terms of size, this church was built in the fifth century A.D. and it has a floor plan of 60 x 34 m with three naves: the western side presents a large *atrium* as several other churches in *Νέα Αγχίαλος*, several "back rooms," and the third baptistery of the city. "Basilica A" was also provided with a protective wall that transformed it into a sort of fortified citadel within the larger *Νέα Αγχίαλος*. Bricks that can be dated to the fifth century A.D. have been found in the basilica and they carry the inscriptions *ΕΚΚΛ(ησίας) Θ*Η*Β(ῶν)*: they have probably been produced at the *Market* and they indicate the presence of yards dedicated mainly to religious structures. An *intra muros* cemetery is located in the north-western part of "Basilica A," whose construction started between the fifth century and the beginning of the sixth century A.D.

It is also worth mentioning another basilica *intra muros*, the "Basilica B" or *Basilica of bishop Elpidius* (so-called because of an inscription carrying the name of the *episcopus*). It dates back to the fifth century A.D. and it also had a baptistery (this is the fourth baptistery in the city, dated between the end of the fourth and the beginning of the sixth century A.D.), whose size was slightly smaller than other similar religious buildings (22 x 17 m). On the western side it had a small square room with a hemicycle side, a column in the middle, and evidence of a fireplace: this last element leads to the conclusion that this space was probably where the food for the poor was cooked and distributed.

One more example of urban churches is "Basilica I," located in the north-west of *Θῆβαι Φθία*, much smaller than the others. Emergency excavations have revealed part of the naves and the apse.

In suburban areas, we attest the presence of a well-articulated religious network along the main roads from and to the city. The most important poles of this network are the "Basilica F" or "Basilica Martyrios" and the "Basilica D" or "*Basilica cemetery.*" The first basilica is located south-west of *Θῆβαι Φθία* and is dated to the fifth century A.D. based on an inscription that carries

that date, while on the other hand the mosaics seemed to be dated to the sixth century A.D. According to the *lectio* of O. Karagiorgu, there might have been a mistake in the interpretation of the inscription or the building may have had two phases of construction. The structure was erected on a not well-identified complex of suburban buildings (a villa? a farm?) that fell into disuse at the end of the fourth century A.D. The basilica counted three naves, spaced out by two colonnades, and it was embellished by mosaic pavements and a narthex at the entrance. It also had several "service rooms" as all the other *intra muros* basilicas. The "Basilica D" is the second largest suburban complex and it is situated in the north-western *suburbium* of the city and it was built during the second half of the fifth century A.D. close to one of the most extensive burial areas of *Θῆβαι Φθία*. In terms of stylistic features, the building has a similar architecture to the other *intra* and *extra muros* churches: it is in fact divided into three naves and it presents a narthex at the entrance. The first necropolis attested at *Νέα Αγχίαλος* was located on a side of the hill where the acropolis stood and it was in use until the late fourth century A.D.: after that the burial areas were transferred to the north-western side of the city (by looking at the grave goods those burials can be dated around the 5th–sixth century A.D.) and, as a result, we can also find in this area two of the most important funerary churches of the periphery. The decision to move the site and the inscription *+ΥΠΕΡ ΕΥΧΕΣ ΜΑΡΤΥΡΙΟΥ* founded in the "Basilica Martyrios" seem to point to a topographic memory linked to a martyrial cult.

Νέα Αγχίαλος provides us with an extraordinary variety of Christian monuments of Late Antiquity (Fig. 6), but it also raises a lot of questions mainly related to how the religious structures created space for themselves and developed. A common trait is the presence of annexes around the basilicas, elements that seem to be autonomous from each other (surprising is also the number of baptisteries in relation to the limited size of the urban area). This autonomy cannot be generalized, since in presence of a bishop the management was always centralized, but it

Christian Topographies During Late Antiquity and the Early Middle Ages, Fig. 6 The topography of *Νέα Αγχίαλος* (redrawn after Karagiorgu 2013)

seems also to be confirmed by the location of the center for the production of bricks for the construction of the churches that was situated in the topographic basin of the previous site.

On this matter, it is interesting to note how the epigraphic *corpus* of *Νέα Αγχίαλος* indicates the presence of a very heterogeneous community, characterized by various levels of ecclesiastic hierarchy along with several categories of workers (soldiers, blacksmiths, tailors, farmers, merchants, teachers, mosaicists, etc.). This social structure mirrors a city that, despite its limited size, was fully integrated in the large trade flows of the Aegean Sea (as proved by the relevant number of amphoras of eastern production founded: among those the *Late Roman* 1, 2, 3, 4, confirm fruitful trades with Syria, Cyprus, Cilicia, Gaza, etc.).

In such a vibrant community, the presence of so many religious buildings (and baptisteries) may have filled the need of the various social groups for a worship place to refer to as communities with their own specific characteristics. Besides that, *Νέα Αγχίαλος* was also an important destination of pilgrimage as attested by the relevant amount of phials, called by the diggers "pilgrimage phials," dated between the fifth and the seventh century A.D.

Νέα Αγχίαλος – Θῆβαι Φθία can be then defined as a successful city, even if, as we have seen, the ancient center had been abandoned in the Early Middle Ages and just later on, at the beginning of the twentieth century A.D., was repopulated. The old city, despite the scarcity of sources, represents an extraordinary example of the transformational power of Christian topography. This transformational pattern is characteristic of the late Roman period because of its monumental and precious structures, that is, when the archeological-monumental data explodes in the topography of a site that would have otherwise been fairly modest.

Christianity: Survival and Reemergence

Alexandra Sanmark
Institute for Northern Studies, University of the Highlands and Islands, Perth, UK

Introduction

The spread of Christianity across Europe was a process that took the best part of a thousand years, from the very start of the Middle Ages when traces of Roman Christianity still remained, to the fourteenth century when Christianity was introduced in Lithuania.

Definition

The study of this complex process involves the two key terms of conversion and Christianization. Conversion relates to the personal acceptance of Christianity, while Christianization is used to describe the long-term transformation of a non-Christian society into a Christian one.

Historical Background

The Christianization usually forms an important part of a country's grand, national narrative. Such accounts tend to be rather condensed versions of events, based on medieval written sources. This can be problematic, mainly since these sources do not provide any insight into the experiences of the people being converted. The sources also frequently focus on what can be termed the official conversion, i.e. the baptism of a ruler who created a Christian kingdom and spread the religion to the larger population, via the elite members of society. Well-known examples include the conversions of the Frankish king Clovis I by Bishop Remigius in 496, King Æthelberht of the Anglo-Saxon kingdom of Kent by the Roman missionary Augustine in 597, as well as the baptisms of King Mieszko I of Poland and King Olaf Haraldson of Norway around the turn of the first millennium. There is no doubt that royal conversions were significant moments in history, but in order to get a fuller picture of the Christianization they must be viewed together with the large body of archaeological evidence.

This material shows that medieval Christianization was an extended process, which not only continued after royal baptisms, but which also started long before the first documented missions. At this time, pagan peoples were in frequent contact with the Christian world and in this way gradually built up their knowledge of the religion and its practices. It must be assumed that individuals converted to Christianity at this early stage, and over time, the number of practicing Christians gradually increased, although this was not a linear development. It was this phase, which in many cases lasted several hundred years and is referred to as the infiltration phase, that led up to the royal conversions described in the written sources. Earlier missionary activity is at times mentioned in the accounts, but these sources do not provide detailed insights into cultural contact and exchange between peoples or the acceptance of Christianity by the wider population.

The archaeological evidence of Christianization cannot be treated as a simple reflection of

religious affiliation, but each piece must be considered and examined within its own context. This type of evidence can, however, be seen to express variations of a Christian identity. The manifestation of Christianity through material culture is not uniform, as the religion forms but one part of a person's identity, together with other identities, such as age, gender, and status, with further variation added by political affiliation and local expression. Despite this, three main types of archaeological evidence can be used to examine the spread of Christianity on a general level. These are: ecclesiastical buildings, burial practices, and artifacts with Christian symbols.

Early churches are traced in the archaeological evidence via cruciform, equal-armed, apsidal, narrow-ended, or at times simple rectangular buildings, all east-west aligned. These structures were made of wood or stone, depending on the geographical area, with stone buildings generally becoming more common as Christianization moved on. Rectangular buildings found underneath later churches, are often interpreted as churches too, but these identifications are less certain.

Burial evidence has formed an important core of evidence for the study of Christianization. Christian influence has been traced, for example, in the disappearance of grave-goods and the shift from traditional burial grounds to Christian cemeteries. The foundation for this approach has been the assumption that burial is always a religious act. This does not necessarily follow, especially not in the early Middle Ages, when the church did not require any certain modes of burial. At this time, Christian burial was instead a privilege open to the elite members of society. Grave-goods were fully compatible with Christian burial, as evidenced in churches and church yards across the Middle Ages and variations in the amount of grave-goods have now been linked to social, rather than religious change. It was not until the High Middle Ages that Christian burial started to become a legal requirement and even then it was generally just stated that the dead should be buried in church yards. Despite these differences over time, across Europe the shift from traditional burial grounds to church yard burial was a rather protracted process. Traditional burial practices were important for ancestral reasons and expressions of power, and many people most likely wished to hold on these. The burial record is therefore unlikely to provide a direct reflection of religious change.

Artifacts that carry Christian symbolism, e.g., stone crosses and memorial stones with Christian symbols and text, and portable items, such as crucifixes, chalices, croziers, can be seen to show a growing local Christian identity, as well as contacts with the wider Christian world.

History of Research

In this entry, the spread of Christianity is examined through four case studies, each of which represents a version of the different types of Christianization that took place across medieval Europe. Two of the areas, Merovingian Frankia and Anglo-Saxon England, were part of Roman territory until the fifth century. In Frankia, after the decline of the Empire, Christianity remained in a relatively strong position, while in Anglo-Saxon England the religion seems to have more or less disappeared. Despite the shared Roman legacy, clear differences in early Christian practices developed. The other two areas, Scandinavia and most of Saxony, were never Romanized, and there was therefore no Christian legacy to make use of in the creation of churches and holy sites. Saxony, in particular, stands out as this area was violently Christianized by Charlemagne's conquest in the late eighth century, whereas in the other areas people were actively acquiring the religion from early on, albeit often with external aid or pressure. Scandinavia, on the other hand, was one of the last areas of Europe to be Christianized and here the effects of long standing contacts with the Christian world are particularly clear.

Frankia: In the late Roman period, Christianity was above all practiced in the urban areas. At this time, the fortified cities were equipped with churches and bishops, as seen in Tours and Trier where cathedrals were constructed in the fourth century. After the decline of the Empire, the

religion remained strong in the cities, and even continued to grow, especially in southern and central Gaul. Archaeological evidence demonstrates that Christianity was spreading on a wider scale from the sixth century, perhaps given a boost by the conversion of King Clovis I. At this time, some of the Roman churches within the city walls were still standing and were taken back into use, as, for example, at Tours where both the cathedral and episcopal residence had survived, together with the Basilica of St Martin, which was refurbished in the 550 s. Roman secular buildings were also converted for ecclesiastical use, famously seen at St Pierre-aux-Nonnains in Metz and the monastery of Oeren in Trier. In addition, suburban churches were erected near the city walls, in Lyon and Trier, for example, several such churches appeared during the Merovingian period.

Another common development took place outside the city walls, in the traditional Roman burial grounds. *Ad sanctos* burial, i.e., burial in proximity to holy relics, was an important concept in this period and churches were therefore constructed on top of tombs of Roman saints and martyrs. Clovis I was buried in such a church, above the tomb of St Geneviève, in a cemetery outside Paris. Sites of this kind became popular foci for early Christian burials, as seen at Arles, Lyon, Tours, and Vienne, and these cemeteries at times held thousands of graves.

From the sixth to the eighth century, Christianity spread from the cities to rural areas, where churches were founded by aristocrats on their private estates. The nature of the early churches varies: some were funerary chapels built in traditional cemeteries, others were converted Roman villas and others still were family monasteries. Many of these churches had "founder graves," prominent burials in a central position of the building. Over time, some of these propriety churches gained in status and became parish churches serving the wider community.

From the sixth century, the Roman ban on intramural burial was starting to break up with the new tradition of furnished elite burials in churches, e.g., in the cathedrals of St. Denis, Arlons, and St. Germain-des Près. Other well-known examples are the sixth-century burials in Cologne Cathedral. Here a grave chamber was found, with a coffin containing a woman's body with an elaborate headband made with gold thread, dress fasteners, and an amulet container. Vessels of glass, pottery, and bronze had been deposited next to the coffin. Another burial contained a boy equipped with a helmet, various weapons, a wooden object interpreted as a scepter, as well as a bed and a chair.

In society as a whole, from the fifth and sixth centuries, burial practices were also changing, as traditional burial grounds were gradually abandoned in favor of *ad sanctos* burial, although this did not become the norm until the eighth century. It is, however, possible that wooden churches were erected in some traditional cemeteries, as has been suggested after the excavations at Sézegnin and Grobbendonk. In northern Gaul, circumstances were slightly different as the traditional "row-grave" (*Reihengräber*) cemeteries continued as the main form of burial into the seventh century (Halsall 2010).

The great variation in Frankish early medieval burial practices is illustrated by Hordain (northern France), which is a cemetery with over 400 burials dating from the late fifth to the end of the seventh century. The northern part, where the earliest burials are located, has been interpreted as the pagan zone. Here, graves were on a north-west alignment and two graves contained horses. The next identifiable phase, seen as the Christian one, started in the mid-sixth century, when east-west aligned burials appeared in a different area, and around the year 600, a church, an east-west aligned building with an altar, window glass, and a wealthy founder grave, was erected. At this site, no transition between different types of burial was seen, but instead throughout the lifespan of the site, burial continued in the two areas, keeping their respective orientations.

Until the middle of the seventh century, items with Christian symbolism were rare in Frankia. From this time, cross-shaped brooches on female dress started appearing in burials, and occasionally settlements, among the East Franks between the rivers Rhine and Mosel. This tradition seems to be connected to late Roman Christian practices in northern Italy, which were still present in the fifth and sixth centuries. Among the western Franks, there is no evidence that cross-shaped brooches were worn.

Anglo-Saxon England: In the Roman period, Christianity does not seem to have been a major religion in England. The strongholds were in the urban centers and their hinterlands, while in rural areas, Christianity was more mixed with pagan religion. After the decline of *Romanitas*, the British Church, which had developed from Romano-British Christianity, was pushed westward to Wales and Cornwall by invading pagan Anglo-Saxon tribes. As a result, very little Christianity remained in England.

Material culture and burial practices demonstrate that the newly settled Anglo-Saxon tribes identified with pagan Germanic traditions and peoples of the north, but towards the end of the sixth century, their attention shifted to the Christian world and Frankia in particular. From this time, mainly Frankish, but also Roman and Byzantine, artifacts started appearing in England. In the light of this, King Æthelberht's invitation of Roman missionaries seems logical, and Augustine, who was to become the first bishop, arrived in 597 (Morris 1997).

The Anglo-Saxon fascination with Frankia and Roman Christianity led to some similar developments in terms of early Christian foci. One of the clearest examples is the old Roman town of Canterbury, reawakened as the first Anglo-Saxon episcopal seat. In the sixth century, a cathedral was constructed inside the walls, reusing an old Roman building, possibly a church. Outside the walls, in the Roman inhumation cemetery, a new Christian focus, which was to become the largest Christian cemetery of Canterbury, emerged. In the sixth and seventh centuries, the Church of St. Martin was created here from a remodelled Romano-British structure, together with the monastery of SS Peter and Paul and St. Augustine's Abbey. No other Anglo-Saxon examples of towns following the Roman tradition of extramural burial are known. In other towns of Roman origin, such as Leicester, York, Rochester, and London (the area around St Paul's Cathedral), however, the model with churches erected within the center was followed (Morris 1997).

In rural areas, churches started to appear from the seventh century. From this time and throughout the early Anglo-Saxon period, the term minster (from Old English *mynster*) was used for any type of religious community, from churches with priests to monastic houses and any other ecclesiastical settlement. The minsters were aristocratic foundations, which quickly became important Christian centers, of which some survived as parochial mother-churches in the later Anglo-Saxon period. They made a strong visible impact on the early Christian landscape in England and were located in carefully chosen spots, with hills, peninsulas, and confluences being particularly common. The material culture from eighth and early ninth-century minsters, including Jarrow and Barking, is distinctive, with finds such as book and shrine mounts, styli, imported pottery and glass vessels (Blair 2005).

The reuse of Roman buildings and masonry was frequently occurring. Roman forts were popular choices, e.g., Bradwell-on-Sea and Reculver (Kent), where churches were erected in the seventh century. The reuse of forts was presumably driven by the desire for Roman remains together with the practical need for an enclosure around the church. A combination of written sources and excavations have shown that within the enclosure space was rather tight, at times with subsidiary chapels, oratories, and domestic buildings. Other major types of Roman remains adapted as churches were large villa complexes (e.g., Castor, Northamptonshire and Cheddar, Somerset) and martyria. Early medieval churches constructed on top of martyria include those at Wells (Somerset) and Stoneby-Faversham (Kent). St. Alban's Abbey (Hertfordshire) may be the only known example of Christian continuity from Roman to Anglo-Saxon times. Outside Roman Verulamium, a Roman basilica erected over the grave of St. Alban continued in use through the early Anglo-Saxon period (Morris 1997).

Prehistoric sites and monuments became foci for early churches too. The most significant types include earthwork forts (e.g., Hanbury in Worcestershire and Breedon-on-the-Hill in Leicestershire) and mounds (e.g., Taplow in Buckinghamshire). Some of these monuments may have functioned as pagan Anglo-Saxon cult sites, although in most cases this is very difficult to prove. The most certain case is Bampton in Oxfordshire, a minster dating from the tenth century or earlier, constructed in relation to a cultic complex including Bronze Age barrows and a

pagan or conversion-period cemetery dating from c. AD 700. In contrast to Frankia, however, there is an almost complete lack of evidence of Anglo-Saxon churches erected in traditional cemeteries (Semple 2013).

Anglo-Saxon burial practices were gradually changing at this time. In some cases, for example, Shudy Camps (Cambridgeshire) new areas were added to existing burial grounds. More commonly though new, rather small, cemeteries without churches were created, as seen at Lewknor (Oxfordshire) and Bromfield (Shropshire). As in Frankia, the allure of *ad sanctos* burial seems to have led to a voluntary shift of burials to minster sites. Some of the earliest minster burials took place shortly after 700 at Minster-in Thanet (Kent), Winchester (Wessex), and Waltham (Essex). By the middle of the ninth century churchyard burial was becoming the norm, and some of the minster cemeteries grew were very large, capturing the population from the surrounding areas (Blair 2005).

The lack of a consistent expression of Christianity in the seventh and early eighth centuries is further demonstrated by the female burials with Mediterranean style jewelry and cross pendants. Despite their different characteristics, these graves are all seen as Christian; from the richly furnished grave at Swallowcliffe Down (Wiltshire) inserted into a Bronze Age barrow to the more sparsely furnished examples, such as the one found in a traditional cemetery in Lechlade (Gloucestershire), and the burials at Ixworth (Suffolk) and Desborough (Northamptonshire). These burials represent the transitional stage to elite minster burial, and in terms of grave-goods, the most appropriate parallel is the seventh-century burial of St. Cuthbert with a pectoral cross. The pieces of jewelry from these graves are some of the most striking, early Anglo-Saxon examples of artifacts with Christian symbols (Blair 2005).

Saxony: Charlemagne's conquest and Christianization of Saxony lasted between 772 and 805. The neighboring areas in the south and west had already been recently Christianized by the Franks, and although less violent, some similar strategies can be identified. One of the main schemes was the speedy establishment of bishoprics, as seen in Utrecht, Büraburg, Würzburg, and Erfurt. These episcopal sees were in carefully chosen locations, often reusing established strongholds. Excavations have demonstrated that both Büraburg and Würzburg were erected close to, or on top of, hilltop fortifications with important political and religious functions. In the Christian era, these bishoprics became important centers for administration, manufacture, trade, and not least for missionary and military activity. In Saxony, during the reign of Charlemagne, bishoprics were founded in, e.g., Verden, Osnabrück, Minden, and Bremen, with, e.g., Hamburg and Hildesheim added during the reign of his successor, Louis the Pious. Excavations have revealed that Hamburg was erected on top of an older Saxon fort and that the Church of Christ the Savior at Paderborn, constructed as part of the royal palace, was erected above the remains of an extensive wooden structure. Many of these early episcopal seats, such as Paderborn and also Münster, were surrounded by fortifications (Stiegemann and Wemhoff 1999; Stiegemann, Kroker and Walter 2013).

Excavations have shown that the earliest churches in Saxony were rather simple rectangular structures with a rectangular choir. One such example is the first church at Paderborn which consisted of a 25-meter long nave, a chancel in the east and an atrium in the west, and with a cemetery inside and outside the atrium. This and other palaces with churches attached were erected with conscious style references to Roman antiquity, perhaps making up for the lack of Roman remains to reclaim as part of the Christianization. In addition, altar relics for the new churches were brought to Saxony already from the late eighth century. The body of St. Liborius was translated to Paderborn in 836, and as revealed by modern excavations, was buried in a ring-shaped crypt in the western transept of the cathedral.

Not all churches founded in the late eighth and the ninth centuries were cathedrals, but some were presumably proprietary churches built by Frankish and Saxon nobles in their own settlements. At this time, both stone and wooden churches were erected. A particularly early example is Oldenstadt, Stadt Uelzen, Niedersachsen where the first phase of the wooden church dates from around 800. Other such examples of wooden churches are Tostedt, Niedersachsen, originating

in the early ninth, and the St. Amandus Church in Aschendorf, which was built a few decades later.

As part of his violent conquest Charlemagne introduced an extremely harsh law known as the *First Saxon Capitulary* in which practices regarded as pagan, such as cremations and mound burial, were outlawed. According to this law, people should instead be buried in "church cemeteries." Despite this piece of legislation, the changes in burial practices in Saxony are rather similar to those seen other areas. The most common solution was to use specific areas of the traditional burial grounds, as seen at Ketzendorf, Maschen, and Oldendorf. Churchyards were few and far between at this time, although some examples are known: at the church in Oldenstadt, burial started around 800, while at the St. Amandus Church and the St. Firminius Church, Dötlingen Oldenburg, Niedersachsen, the first burials date from the middle of the ninth century, and the ninth or tenth century, respectively (Stiegemann and Wemhoff 1999; Stiegemann, Kroker and Walter 2013).

Various types of artifacts with Christian symbolism are found in the wake of the Carolingian conquest and missionary work. Variants of the Carolingian cross-shaped brooches (*Kreuzfibel*) appeared in Saxony for the first time at the end of the eighth century, for example, in the cemeteries of Paderborn and Drantum near Oldenburg. During the ninth century, square, rectangular, and disc-shaped brooches with cross motifs appeared in graves and settlements, together with other types of brooches with Christian symbols. The cross motif is found on other objects too, such as the Tating ware jugs retrieved from excavations in Paderborn (Carver 2003).

Scandinavia: The three Scandinavian countries of Denmark, Norway, and Sweden were officially Christianized by their respective kings around the turn of the first millennium, but archaeological evidence shows that the area had long-standing contacts with the Roman Empire and the wider European Christian culture. Examples include the Migration-period book-shaped pendant from Hög Edsten, Bohuslän, Sweden, the sixth-century Coptic ladle and the eighth-century Irish Crozier found on the island of Helgö, Uppland, Sweden (Carver 2003).

The archaeological evidence of the process of Christianization is varied. Late Viking-age runestones from across Scandinavia are among the most important pieces of evidence. These monuments are generally interpreted as Christian as they almost exclusively have a Christian message in the inscription and/or the iconography. One of the most famous examples is the runestone from Jelling in Denmark where King Harald Gormson "Bluetooth" claimed to have Christianized the Danes. The decorations on this stone include an image of Christ (Nilsson 1996).

The first major phase of church building in Scandinavia took place in the eleventh century. Most of the earliest churches in Scandinavia were presumably built of wood, which in Denmark and Sweden were replaced by stone churches, above all in the twelfth and thirteenth centuries. Many of the early wooden churches are difficult to find archaeologically as they are located underneath the later stone churches. Excavated examples include Jelling and Snoldelev in Denmark. In Sweden, the presence of a particular type of eleventh-century grave monument found in connection with stone churches often indicates the existence of an earlier wooden church (Nilsson 1996).

The first stone churches in Denmark date from the first half eleventh century, e.g., Roskilde cathedral and St. Jørgensbjerg church, while in Sweden, one of the earliest stone churches was built in Sigtuna at the end of the eleventh century. Other early stone churches in Sweden, such as those in Herrestad, Örberga (Östergötland), and Sigtuna (Uppland), all date from the first half of the twelfth century. In Norway, wooden churches continued to be the norm for several centuries after the introduction of Christianity, with some famous stave churches still standing, e.g., Lom (Oppland) and Heddal (Telemark). Bø in Telemark is a rare Norwegian example of a twelfth-century stone church with remains of a wooden predecessor underneath. Across Scandinavia, early churches were often erected on farms and may therefore have been proprietary churches, of which some later became parish churches.

At least some churches were erected in the immediate vicinity of prehistoric monuments. One clear example is Hørning in Denmark, where an eleventh-century wooden church was

erected on top of a levelled burial mound, below which there was a chamber grave, dating from c. 1000 and containing a woman and large amounts of grave-goods. The closeness in time between the burial and the building of the church strongly suggests that the church was deliberately placed on top of the flattened mound. Another striking example is Frösö Church (Jämtland, Sweden). Underneath the high altar, large amounts of animal bones and the charred remains of a tree was found, which has been interpreted as evidence of a Viking-age cult site. Another interesting example comes from Mære (Trøndelag, Norway), where a twelfth-century church was built on top of a rectangular Viking-age building, which most likely had cultic functions. The establishment of the first Swedish episcopal see at the former cult site of Gamla Uppsala, Sweden, is also significant, although there is no direct archaeological link between Christian and pagan activities. This is, however, a clear example of the church taking over a site with important functions in the former pagan cult (Nilsson 1996).

As seen elsewhere, burial practices were changing rather slowly. It is likely that in eleventh and twelfth-century Scandinavia, church yard burial was required by law, but this was clearly not enforced, presumably as churchyards were too few and far between. Instead, as was the case elsewhere, traditional burial grounds continued to be used for burial. A Norwegian example is Haug, Hadelsøya, Nordland. An example of a particularly long-lived cemetery in Sweden was Valsta (Uppland, Sweden) which was used into the twelfth century. In some cases, such as Stav and Hässelby (Uppland, Sweden), possible Christian zones have been identified in the outskirts of the cemeteries. These areas contain graves marked by rectangular stone-settings and represent the last phase of burial on the sites (Nilsson 1996).

Delimited Christian cemeteries without churches also occurred from the tenth century, as seen at Birka (Uppland), Såntorp (Västergötland), and in the outskirts of Sigtuna, Sweden. Another example comes from Grødby on the Danish island of Bornholm, where a cemetery has been coin-dated to the reign of Sven Estridsen, i.e., 1047–1076.

Another development was the erection of churches in existing Christian cemeteries, as, for example, seen in Norway, where several churches from the second half of the eleventh century are located in Christian graveyards which date from the first half of the eleventh century, or even the tenth century (Nilsson 1996).

Church-yard burial became the most common form of burial during the twelfth century, although some church yards, such as St Stefan's and Löddeköpinge (Skåne, Sweden), Peter's Church in Tønsberg (Vestfold, Norway), and Gamlebyen in Oslo came into use during the tenth and the first half of the eleventh century. Remarkably, early are the graves from the churchyard around Ribe Cathedral, Denmark, where the earliest phase of burials date from the ninth century to the middle of the eleventh century.

Graves containing artifacts with Christian symbols appeared above all from the late eighth to the eleventh century. Examples include Tating ware jugs, croziers, crosses, and crucifix pendants, as well as reliquaries, some of which had been reused as fibulae. Many of these objects come from female burials suggesting that Christianity played an important role for certain groups of elite women. One particular example comes from Birka, Sweden, where eight of nine pendant crosses were found in female graves dating from the first half of the tenth century. Several of these crosses are of "simple, almost poor" craftsmanship. This is not usual for Viking Age jewelry, and it therefore seems that the symbolic value of the crosses was greater than their value as pieces of jewelry, although the purpose of these grave-goods is of course unknown (Nilsson 1996).

Future Directions

This survey of the spread of Christianity in Europe, examined via four case studies, clearly demonstrates that the process of Christianization, despite the different features and characteristics, on the whole share a number of traits, visible in the archaeological material. One clear observable difference is that in the areas that had not been Romanized the official acceptance of Christianity took place at a later stage, demonstrating the significance of the infiltration phase for this process. Overall archaeological evidence is crucial for the

study of Christianization as it provides insight into the pagan peoples that are being converted, as well as numerous groups of people at different levels of the new, Christian societies. On a more individual level, great differences are naturally found between the different geographical areas, and future research is likely further to emphasize the variability in the processes of Christianization and Christian practices across Europe.

Introduction

Today's students of archaeology might find it difficult to imagine an era when modern chronometric dating methods – radiocarbon and luminescence, for example – were unavailable. How, the students might ask, were archaeologists working, say, in the first half of the twentieth century able to place objects and sites in a chronological sequence? Given the important roles that chronometric methods play in modern archaeology, together with the precision they often seem to impart, it is little wonder that students of today might view earlier efforts to establish temporal control as rather crude and outdated. Such a view, however, overlooks the fact that early archaeologists devised a battery of clever methods to determine the ages of archaeological phenomena with considerable precision. This kind of chronological control is often referred to as *relative dating*.

Definition

Relative dating can be defined as the production of a sequence of events for which no fixed or calendrical dates exist. Instead of knowing that a certain kind of pottery was made between, say, CE 200 and CE 400 and that another kind was made between CE 400 and CE 600, all we know is that the latter kind is of more recent origin than the former. The latter kind could postdate the earlier one by several hundred years or by a thousand years, but we do not know this. All we know is that it is more recent. Similarly, we might know, perhaps through historical evidence, the terminal calendrical date of manufacture and use of the later kind of pottery, but we might not know when on a calendrical scale that kind of pottery was first made and thus when it began replacing the earlier kind. In contrast, *absolute-dating* methods – sometimes referred to as *chronometric* methods – yield the amount of time, within the limits of sampling error, that elapsed between each pair of events as well as a calendrical date indicating when each event occurred and perhaps each event's duration as well.

Absolute-dating methods thus provide more than a simple chronological sequence, but they in no sense render relative-dating methods obsolete. There are situations where the latter are preferable, especially when large areal chronologies are desired. Relative-dating methods are inexpensive, as opposed to methods such as accelerator

mass spectrometry radiocarbon dating, which may cost as much as $1,000 per sample. Unfortunately, few modern archaeologists have more than a passing acquaintance with the origins of relative-dating methods and as a result have by-passed some of the most innovative work ever undertaken in archaeology. That research is as relevant today as it was a century ago.

Historical Background

Numerous methods for working out relative chronological orderings have been devised in archaeology, one of which, stratigraphic excavation, has its roots in geological observations of the eighteenth century. *Stratigraphic excavation* is perhaps the best known of the various relative-dating methods used by prehistorians, no doubt because the majority of the archaeological record has a geological mode of occurrence (O'Brien and Lyman 1999). There are also two other methods – *seriation* and *cross dating* – that likewise deserve attention. All of them, however, depend on *artifact types*, especially those that pass the *historical significance test*. This means that a type comprises specimens that were made during a single, relatively short interval of time and that the frequency distribution through time of the specimens approximates a unimodal curve (Fig. 1). Such a curve reflects the introduction of a type, its growth in popularity, and its decline and eventual disappearance. Any type that passes the test is referred to as a *historical type*, the gold standard of relative-dating methods.

Chronological Systems, Establishment of, Fig. 1 Diagram showing temporal alignment of three hypothetical pottery types from latest (black) to earliest (white) (From O'Brien and Lyman 1999)

Key Issues

Stratigraphic Excavation

Stratigraphic excavation is defined as removing artifacts and sediments from vertically discrete three-dimensional units of deposition (strata) and keeping those artifacts in sets based on their distinct vertical recovery proveniences for the purpose of measuring time (Lyman and O'Brien 1999). Vertical boundaries of spatial units from which artifacts are collected can be based on geological criteria, such as sediment texture, or on metric criteria, such as elevation. Stratigraphic excavation is based on the commonsense assumption that in a sedimentary column, strata stacked one on another represent the passage of time. More specifically, the assumption is that strata at the bottom of a column were deposited before those above. This is known as the *law of superposition*. Unfortunately, archaeologists often fail to realize that depositional history does not necessarily represent the *age* of the sediments themselves. This includes objects in those sediments. Although artifacts in one stratum were *deposited* before those in a higher stratum, it cannot be assumed that artifacts in the lower stratum are *older* than those in the higher stratum. It could be the case, for example, that artifacts from one period were eroded from one locality and deposited downslope on top of artifacts from a later period.

Thus, superposition is an indirect dating technique when applied to artifacts within strata. It is indirect because the ages of the artifacts are *inferred* from their vertical positions relative to

one another. Another way of saying this is that the target event is the age of an artifact's creation whereas the dated event is the age of the depositional event. The work of the archaeologist, like that of the geologist, is to analyze the superposed sediments and to determine when strata were deposited as well as when the sediments were formed. Archaeologists are interested in culturally derived sediments – artifacts – but they realize that the artifacts usually occur within noncultural (natural) sediments. The nature of the latter often is an important source of information relative to the nature of the former.

The problem of identifying the first stratigraphic excavation may never be solved, but historians of archaeology often point to Thomas Jefferson's 1784 excavation of a trench through one of the earthen mounds on his property in Virginia. He subsequently made notes on the stratigraphic relation of layers of earth and human bones in the mound and remarked on the chronological implications of the layering (Jefferson 1801). Jefferson's work was later said to have anticipated modern archaeological methods by a century, but it had no particular impact on Americanist archaeology. As the British archaeologist Mortimer Wheeler (1956: 59) later observed, "Unfortunately, this seed of a new scientific skill fell upon infertile soil. For a century after Jefferson, mass-excavation remained the rule of the day." It was 75 years later, and then in Great Britain, that Jefferson's approach was reinvented with effect. There, on the Devonshire Coast, the excavation of Brixham Cave of England by prominent British geologists and paleontologists in 1858 focused explicitly on stratigraphic context.

In North America, stratigraphic excavation became an art form during the second decade of the twentieth century through the efforts of two prehistorians working in New Mexico, Nels Nelson of the American Museum of Natural History in New York and Alfred V. Kidder of the Robert S. Peabody Museum in Andover, Massachusetts. Nelson started working at San Cristobal, an abandoned pueblo in the Galisteo Basin south of Santa Fe, New Mexico, to test a suspected local sequence of pottery types. In his report, Nelson (1916) stated that by the beginning of the 1914 field season, he suspected he knew the chronological order of five types of pottery, two of which exhibited painted designs and three of which contained glazed designs. One of the painted types was suspected of being the earliest of the five because it occurred primarily on small pre-Puebloan sites. The other painted type was known to be the latest of the five types because it occurred in abundance on sites historically documented as postdating the Pueblo Revolt of 1680. Nelson viewed one of the three glazed types as being from the early historical period (1540–1680), given that it was found consistently with bones of horses and other historically introduced domestic animals. The other two glazed types were slid in between the early painted type and the historical-period glazed type. Despite his intuitions regarding the chronological arrangement of the types, Nelson (1916: 162) noted that "tangible proof was still wanting." He found that proof at San Cristobal.

Nelson excavated San Cristobal in arbitrary 1-foot-thick levels rather than in natural stratigraphic units, and he kept sherds from each level separate. This is the feature of his work that has received attention in histories of Americanist archaeology (O'Brien 2003). Nelson had visited the stratigraphic excavations of European prehistorians Otto Obermaier and Henri Breuil in Spain in 1913 and had seen levels marked off on the walls of the excavations, and he had participated in excavating Castillo Cave – an experience that, according to Nelson, served as inspiration for his excavation method at San Cristobal. His technique of excavating in arbitrary levels might have come from Europe, but certainly not the notion that superposed collections marked the passage of time. Everyone knew that. The innovative aspect of Nelson's work was his demonstration that pottery types altered in absolute frequency through time in a pattern that he characterized as "very nearly normal frequency curves [that reflected the fact that] a style of pottery…came slowly into vogue, attained a maximum and began a gradual decline" (Nelson 1916: 167).

Chronological Systems, Establishment of, Fig. 2 Nels C. Nelson's pottery data from Pueblo San Cristobal, New Mexico, showing the waxing and waning popularity of types. Note that Nelson believed, correctly, that the frequency of corrugated ware was not a good indicator of age. Note also the essentially monotonic frequency distribution of his types I–III (After Nelson 1916)

Figure 2 shows Nelson's data graphically as percentages of four pottery types by excavation level. Three of his types – I–III – are of particular chronological usefulness in that they have continuous distributions in time: they come into being and they gain in popularity until they reach their zenith, at which point they begin to fade in popularity until they finally disappear [AR1]. In short, they are good historical types, useful for marking the passage of time. Corrugated ware does not follow this pattern and thus is not a good historical type.

Kidder, who was working at Pecos Pueblo, just to the east of the Galisteo Basin, took notice of Nelson's chronological ordering of pottery types. Kidder had chosen Pecos as his focus of study because historical documents indicated it had been occupied from 1540 until 1840, and preliminary surface reconnaissance had suggested that it had practically all the prehistoric pottery types identified up to that point in the Rio Grande drainage of northern New Mexico:

> [I] hoped that remains [at Pecos] would there be found so stratified as to make clear the development of the various Pueblo arts and to enable students to place in their proper chronological order numerous New Mexican ruins whose culture has long been known but whose relation to one another has been entirely problematical. This hope was strengthened by the fact that Mr. N. C. Nelson . . . had recently discovered very important stratified remains at San Cristobal a few miles to the west (Kidder 1916: 120).

Similar deposits at Pecos would allow comparative analyses and the extension of Nelson's chronology, which ended at 1680 when San Cristobal was abandoned, into the middle of the nineteenth century.

Early in his excavations, Kidder (1916: 122) recognized that pottery types in the lower levels of his trenches were "markedly different from [those] at the top and that there were several distinct types between." Not all excavations at Pecos Pueblo were undertaken with close attention to superpositional relations. Rather, such relations were observed by "tests made at different points as the [excavation] advanced. The tests consisted of the collection of all the sherds in a given column of débris, the fragments from each layer being placed in a separate paper bag" (Kidder 1916: 122). During the first year's field season – the summer of 1915 – those tests employed arbitrary levels that were 1–1.5-ft thick, but when it was apparent that the arbitrary levels split visible strata, "a new bag was started," which apparently meant that Kidder paid attention to the stratigraphic provenience of the artifacts found within his arbitrary levels (Lyman and O'Brien 1999).

After the first field season, Kidder excavated Pecos Pueblo strictly in visible stratigraphic layers. He not only listed the absolute frequencies

of pottery types against their vertical provenience in tabular form, as Nelson had done, but he also graphed the changes in relative frequencies of pottery types against his excavation levels (Kidder and Kidder 1917). This analytical technique was later referred to variously as "ceramic stratigraphy" or "percentage stratigraphy" (Willey 1939; Ford 1962). One of his graphs is shown in Fig. 3. Upon inspection of the graphs, Kidder and Kidder (1917: 341) noted that many, but not all, types displayed "approximately normal frequency curves," echoing Nelson in interpreting such curves as "indicating that each [type] had a natural rise, vogue, and decline" (Kidder and Kidder 1917: 349) – the popularity principle (Lyman and O'Brien 1999). In other words, they were good historical types.

Seriation

More than perhaps any other archaeological method, seriation has had a complex history. Textbooks often credit British archaeologists for introducing seriation into the United States, but in reality only one seriation technique – *evolutionary seriation* – was in use in nineteenth-century Britain, and although that technique was eventually introduced to American archaeologists, it differs significantly from the kind of seriation invented by Americanists in the second decade of the twentieth century. That distinctly American kind of seriation is known as *frequency seriation*, and it eventually led to the Americanist development of what is known as *occurrence seriation*.

Regardless of specific technique, seriation is a descriptive method that orders things – here, artifact assemblages – in a column. Seriation creates a linear order, but that order tells us only that the odds are good that two adjacent things are more alike than either is to things farther up or down the order. Seriation is used in archaeology for chronological purposes, but whether or not an order reflects the passage of time is an inference; it is not axiomatic. The term "seriation" is sometimes used as a synonym for "percentage stratigraphy," but this conflates two entirely different procedures. John Rowe (1961: 326) specifically excluded the use of superposed strata in his definition of seriation:

> [T]he arrangement of archaeological materials in a presumed chronological order on the basis of some logical principle other than superposition. . .. The logical order on which the seriation is based is

Chronological Systems, Establishment of, Fig. 3 A broken-stick graph of data from Pecos Pueblo, New Mexico, showing the fluctuating frequencies of pottery types over vertical space (time) (From O'Brien and Lyman 1999; redrawn from Kidder and Kidder 1917)

> found in the combinations of features of style or inventory which characterize the units, rather than in the external relationships of the units themselves.

This definition underscores that an ordering is based on formal attributes of the materials used in the seriation. That is, seriation is based on intrinsic properties of artifacts and not on their relative vertical positions in a column of sediments, which are an extrinsic property. Another way of saying this is that seriation is a direct-dating method whereas superposition is an indirect-dating method.

Evolutionary seriation is virtually identical to the technique of paleontologists, who arrange fossils of similar form in an order such that change in character states of the fossils is gradual and continuous. Perhaps the earliest use of evolutionary seriation was by John Evans, who seriated gold coins from Great Britain that were minted prior to and after the Roman invasion of Britain in 54 BCE. Evans (1850) used changes in two characters or dimensions of variation to seriate the coins – weight and design. A third dimension, die size, did not produce particularly useful results. Not visible in Evans's seriation (Fig. 4) is the decrease through time in coin weight. For example, Type 2 coins on average weighed 103.5 grains, Type 3 coins 91.5 grains, and Type 4 coins 87.25 grains. Highly visible, though, is the change in design on both sides of the coins. The sequence begins with the natural-looking laureated bust of Phillip II of Macedon on the obverse and a horse-drawn chariot on the reverse. Through time, the designs on both sides became successively more stylized until a point was reached at which they again became naturalistic.

Thus far I may observe at present that the coins generally recede farther from the prototype as the places of their discovery recede from the southern coast – as, for instance, the Yorkshire and Norfolk types Nos. 24 and 16 – and that in the southwestern counties the workmanship of the coins appears continually to have deteriorated; while in the southeastern and eastern, after declining for a time, it again improves, probably through the introduction of foreign artists, till, under Cunobeline, it attains its highest perfection (Evans 1850: 137).

Similarly, British archaeologist Sir William Matthews Flinders Petrie used evolutionary seriation, together with a novel grouping procedure akin to occurrence seriation, to make chronological sense out of some 4,000 predynastic burials from several localities along the Nile River north of the Valley of the Kings in Egypt. The key to Petrie's analysis was finding an attribute that changed states through time and then using that attribute to construct a temporal sequence of pottery forms. This attribute, as it turned out, was vessel handles. Petrie suspected that handles were functional on earlier jars, which tended to be large and bulky, but that through time they had become less functional and more decorative, such that by late in the sequence they were simply adornments: "The most clear series of derived forms is that of the wavy handled vases. . .. Beginning almost globular, with pronounced ledge-handles. . .they next become more upright, then narrower with degraded handles, then the handle becomes a mere wavy line, and lastly an upright cylinder with an arched pattern or a mere cord line around it" (Petrie 1901: 5). This is evolutionary seriation. Once Petrie had the vase sequence worked out, it then became a matter of ordering grave lots based on the vase forms associated with them. Further, vessel types that co-occurred with particular handled-vase types then became markers in their own right and could be used to place correctly other grave lots that did not contain handled vases.

As opposed to evolutionary seriation, frequency seriation is strictly an American innovation. A.L. Kroeber, a student of Franz Boas and the founder of the anthropology department at the University of California, gets the credit, based on analysis of pottery sherds he collected from the surfaces of some 15 sites in the countryside around Zuni Pueblo, New Mexico, in 1915. He noticed that some collections tended to be dominated by "red, black, and patterned potsherds," whereas other collections were dominated by white sherds (Kroeber 1916: 8). He concluded that "There could be no doubt that here, within a half hour's radius of the largest inhabited pueblo [Zuni], were prehistoric remains of two types and two periods, as distinct as oil and water. The

Chronological Systems, Establishment of, Fig. 4 Stylistic changes in British coins proposed by John Evans. The sequence begins with the natural-looking laureated bust of Phillip II of Macedon on the obverse and a horse-drawn chariot on the reverse. Through time, the designs on both sides became successively more stylized until a point was reached at which they again became naturalistic (After Evans 1850)

condition of the sites indicated the black and red ware ruins as the more recent" (Kroeber 1916: 9). Based on historical evidence and on the condition of the sites, Kroeber (1916: 9–10) concluded that concerning "the type and period of white ware and the type and period of black and of red ware, the latter is the more recent [belonging] in part to the time of early American history; the former is wholly prehistoric."

Kroeber's ordering of sites based on relative frequencies of pottery types can best be seen by using an imaginary case, as is shown in Table 1, which lists five historical types – in Kroeber's case, pottery types – across the top and six artifact assemblages (A–F) down the left-hand margin. The numbers in the rows indicate the percentage of a particular pottery type in a particular assemblage. For example, assemblage A contains 10% pottery-type 1, 30% pottery-type 3, and so on. Percentages add to 100% for each assemblage. Table 1 begins with the assemblages in no particular order. The seriation procedure would be to sort the assemblages such that each column of percentages approximates a unimodal frequency distribution, such as is shown in the ordered part of Table 1. Note that it makes no difference if the ordering from top to bottom is "E, C, A, B, D, F" or "F, D, B, A, C, E"; knowledge of the direction taken by time's arrow must come from data independent of the seriation.

Chronological Systems, Establishment of, Table 1 An example of a frequency-seriation procedure

	Historical type				
Assemblage	1	2	3	4	5
Unordered					
A	10		30	10	50
B			50	30	20
C	20		15		65
D			40	60	
E	30	25			45
F			20	80	
Ordered					
E	30	25			45
C	20		15		65
A	10		30	10	50
B			50	30	20
D			40	60	
F			20	80	

Before computing power was available, archaeologists performed frequency seriations by hand. James Ford (1962) suggested using long strips of paper containing bars of length proportionate to the percentage of a particular pottery type in a particular assemblage. Each strip shown in Fig. 5 is a separate assemblage, with bars showing the percentage of each type of pottery contained in that collection. Eleven pottery types are shown on the graph, although no assemblage contains sherds of all 11 types. Once each collection is graphed in terms of type percentages, the strips are moved up and down until a best fit is found, meaning that there are as few violations of the unimodal distribution as possible. That is, the resulting type frequency curves – what Ford (1952: 344) referred to as "'battleship' frequency curves" – are as close as possible to those shown in Fig. 1.

Occurrence seriation, which is based on the presence/absence of historical types instead of on their percentages, was suggested as an alternative to frequency seriation in the late 1950s and early 1960s by Rowe (1959) and Paul Dempsey and Martin Baumhoff (1963). Rowe argued that frequency seriation was subject to sampling problems, and Dempsey and Baumhoff pointed out that low-frequency types may be among the best time indicators and that even the presence of single specimens of certain types could be significant in establishing chronologies. As in frequency seriation, the procedure is to sort the unordered rows – the assemblages – so that each historical type, each column, displays a continuous distribution. We can take the same data shown in Table 1 and reduce it to presence/absence data, as shown in Table 2. The order resulting from meeting the expectations of the seriation model is given in the lower half of Table 2. As in Table 1, the direction of time's arrow is unknown, so the ordering from top to bottom could be either "E, C, A, B, D/F" or "D/F, B, A, C, E." Note that in Table 2 assemblages D and F are identical in terms of the types they contain. They cannot be sorted and must, in this example, be considered contemporaneous.

Chronological Systems, Establishment of, Fig. 5 James A. Ford's thumbs-and-paper-clips method of seriating collections. Each strip of paper represents a surface collection or excavation level; on each strip bars have been drawn to indicate the percentage of each pottery type. The strips are then moved around until the best fit is attained (From Ford 1962)

Cross Dating

Geologists have long used fossils included in units of deposition to correlate those layers across space, often vast amounts of space, and archaeologists have done the same, using *marker types*. The usefulness of marker types is tied to their geographic range – we might desire types that appear over a wide area – but also to their life span (we want types with limited chronological ranges). Not all archaeological types meet these criteria, and in fact, few do. Sidestepping the many complex issues that surround how types are created in the first place (O'Brien and Lyman 1999), suffice it to say that many types have too much variation built into them to serve as much more than gross chronological markers. All too often, when a sherd of a particular pottery type is found in one area, and the finder tries to match it up against a published type description of that type, the match is left than perfect, and the person is left wondering, "Is this or is this not a specimen of that type?"

Once in a while, though, artifact types do fit the bill and become excellent marker types that can be used for cross dating. In North America, one such type is the Folsom point (Fig. 6), which was used to tip spears between about 8950 BCE and 8500 BCE. In the early decades of the twentieth century, purported finds of early tools in North

Chronological Systems, Establishment of, Fig. 6 Three views of a Folsom point made from chert. Specimen is approximately 11 cm long

America were invalidated on various grounds, but the breakthrough came in 1927 when workers from the Colorado Museum of Natural History recovered several small, fluted points in association with the remains of extinct bison (*Bison antiquus*) in an arroyo near Folsom, New Mexico. The stratigraphic association was in a geological context that lay near the temporal border between the late Pleistocene and the early Holocene epochs, or about 11,700 years ago. Even in the 1920s, stratigraphers knew what the glacial-age boundary in the western United States looked like in terms of sediments and strata, and thus the age assessment of the bison kill site was not a shot in the dark (Meltzer 1991). The 19 projectile points unearthed at Folsom were easily recognizable because of the fine flaking and the presence of channel scars, or flutes, on both faces that resulted from the removal of long flakes. It was impossible to confuse this kind of point with more recent kinds, and it instantly became a chronological marker eventually referred to as the Folsom type. Whenever a Folsom point is discovered in the western United States, it is clear that early bison hunters were responsible for its manufacture.

Future Directions

There is a tendency in archaeology, like in many disciplines, to dismiss the work of decades earlier on the grounds that it is outdated and unsophisticated, and nowhere is that more prevalent than in discussions of chronological methods. One might suppose that the work of prehistorians such as Nelson, Kidder, and Petrie does not particularly matter anymore because radiometric dating has alleviated our chronological problems, thus rendering any consideration of seriation, stratigraphy, and marker types moot. Alternatively, one might argue that there are two reasons why knowledge of relative dating is key to successful archaeological research. First, absolute radiometric methods do not solve all chronological problems. One needs to evaluate and test the results obtained from the application of these methods, and relative-dating methods provide one source of test implications. Second, radiometric methods may not always be applicable, given the vagaries of the processes that formed and continue to form the archaeological record.

The chronological work that began in Europe in the nineteenth century, based on the principle of artifacts being used to mark the passage of time, reached a zenith in the American Southwest during the second decade of the twentieth century. Archaeologists can still take much away from the reports that emanated from that work.

Chronopolitics and Archaeology

Christopher Witmore
Classical and Modern Languages and Literatures, Texas Tech University, Lubbock, TX, USA

Introduction and Definition

C*hronopolitics* designate several fields of interest and endeavor that intersect with the pragmatics, production, and perpetual maintenance of particular temporalities. Because these fields oscillate paradoxically, and somewhat precariously, between those pasts that are remembered (ostensibly for present and future generations) and those pasts that are condemned to Lethe (the river of forgetfulness in Hades), they ignite an array of interests and passions, controversies, and disputes, which are negotiated through debate and destruction, regulation, and compromise. Here are not considered the chronopolitics of Paul Virilio (2000) that arise at the end of geography, where the geopolitics of three-dimensional space and the reality of distances are canceled out in a revolutionary shift to the politics of compressed time seen in the quasi-instantaneous exchanges of images and sounds, exemplified in the amplification of optical surveillance and advertising across the electronic ether (though the chronopolitics behind the assumption of a wholesale revolution are discussed below). Nor is this topic addressed

in a way that would suggest that those pasts that are remembered are the by-products of human-centered groups enacting their conscious and willful powers of selection. Before further elucidating and exemplifying these chronopolitics, it is important to bring to the reader's attention the old Greek meanings for the constituent words of chronopolitics, *chronos* and *politics*.

Chronos is, in its fullest sense, often translated as "time," and this is the conventional meaning associated with terms such as "chronometer" or "chronology." However, *chronos*, in a more specific sense, is the periodic, ordered, or arranged time; it is the time of classification and metrology. *Chronos* is time as separate from events. It is time as a kind of external parameter. *Chronos* as the ordering is often contrasted with what the Greeks term *kairos*, the time that is more contingent, even chaotic and weather like (Witmore 2007).

As with *chronos*, politics is also considered here in a double sense. Politics centers upon issues raised in a public forum. Here one encounters the old Greek meaning of *ta politika*, which denotes "public matters" or "civic affairs." In a second sense, politics is connected to a kind of curious and probing attitude (Shanks 2004). Taking direction from critical theory (e.g., Leone et al. 1987; also Wilkie and Bartoy 2000), this is politics as a spirit of caution and concern set to expose assumptions and the taken-for-granted myths perpetuated to facilitate control and to extend power and, thereby, its inequities. Politics is not only a matter of worrying over what is best; it is also a matter of crafting "new weapons" (Deleuze 1995). As such, politics is tied to a sustained commitment to effect positive social change as a component of humanistic and scientific responsibility (McGuire 2008).

So, if politics turn around controversies, then chronopolitics follow such controversies through to their realization as temporalities. For want of white space, this article can only touch lightly on many concerns related to *heritage politics* (Harrison 2010); rather, here, chronopolitics are further defined with respect to a particular historicism and its ontological grounds. Admittedly, these *realpolitiks* will leave much of relevance to this field of interest to fall through the cracks.

Key Issues/Current Debates/Future Directions/Examples

The history of modernity centers on the common belief in an arrow of time whose line of flight advances continually from the past to future, thus leaving in its wake an irreversible succession of discrete moments, a line of instants. As a common component of this temporal machinery, the timeline has served as a supposedly external parameter for sorting eras, periods, or epochs and thus ordering time with respect to a series of dates. Therefore, the timeline provides ground for the measure of the past. Consider, for example, the definition of "antiquity" in the 1922 *Palestine Mandate of the League of Nations* as "any construction or any product of human activity earlier than the year A.D. 1700," or take the proposal by the Department of Arts, Heritage, and the Gaeltacht to delist post-1700 CE monuments in Ireland. Routinely measured with respect to the distance from the present, such dates provide hooks from which to hang hierarchies of value. These dates also mask an underlying historicity – something reflected in historic quality, intensity, and prejudice. The Palestine Mandate excludes Late Ottoman Era monuments in Palestine. The proposed delisting of post-1700 monuments rests upon the hard ground of economic bottom line – the burden of the past is just too expensive depending on the economic climate.

There is, of course, considerable nuance to the *chronopolitics* associated with the production and maintenance of the arrow of time. Nietzsche, insofar as it was possible to draw a distinction between species of history, gave us three modalities or uses (1997). The *monumental* celebrated great achievements of the past as exemplary and worthy of imitation. The *antiquarian* sought out every scrap of the past as something to be preserved and revered. And the *critica*l regarded the past is oppressive and condemned it to oblivion. Let us consider Nietzsche's uses in light of a more detailed example.

On December 28, 2006, bulldozers plowed through several mud-brick houses in Gurna, Egypt. This was the last of a series of efforts by the Egyptian government and the Luxor City

Council (backed at various times by myriad politicians, archaeologists, heritage organizations, and development agencies) to relocate the residents of Old Gurna and demolish the group of hamlets set amidst the rock-cut tombs and funerary temples known as the "Theban Necropolis" (Meskell 2005). Now, following Nietzsche, critical history underwrites the destruction of what government officials described as the "ramshackle" houses of a "shantytown" (it should be noted that the demolition of Old Gurna was tied to its "unsanitary" conditions and this has provided a broad rationale for the redevelopment of Egyptian villages since the *gambiae* malaria epidemic of the 1930s and 1940s (Mitchell 2002: 188)). Monumental history (read "heritage") resuscitates voids as tombs from the golden age of the Eighteenth Dynasty (1550 BCE). Locals, for their part, countered the arguments of government officials with an antiquarian history, which emphasized how Old Gurna's vernacular architecture of simple mud-brick houses, decorated with brightly painted scenes of daily life, animals, and Qur'anic verse, constituted their own unique forms of heritage. Drawing a line between the archaeological and non-archaeological, between one past and another taken to be a present intrusion, injects a historical partiality (which, in this case, is itself subservient to an economic agenda) that has no basis in the realities of the past. Each modality also enacts a very different kind of temporality, and, thus, each is implicated in a different set of chronopolitics (consider Hamilakis and Anagnostopoulos 2009).

With monumental history one encounters a cyclical temporality seen in the rise and fall of great civilizations and a hierarchy of value impacted by distance measured in dates, relevance, and, ultimately, tourism. With antiquarian history, one witnesses the cultivation of a continuous temporality (for Nietzsche the laws of fidelity blocked creativity (also Foucault 1984)). With critical history the fabric of time is torn through disjuncture and revolution. Still, no matter which species of history and its associated temporality one embraces, for Nietzsche, all were in service of a peculiar affliction; namely, because moderns believe themselves to have definitively broken with the past, they attempt to preserve and date everything (Latour 1993).

These *chronopolitics* feed into a notion of time as linear, as unidirectional, with man at center, for causality is rooted in historical events and those living in the present never cease to be on the cutting edge (Serres with Latour 1995; also Olivier 2011). Thus the notion that time passes results in a complacent attitude toward the abolition of the past. This is evidenced, for example, in the dynamics of archaeological production. Gestures of elimination and revolution occur when scholars consign other intellectual platforms to the realm of the outmoded, the outdated. Thus a time of transcendence and progression is achieved through contradiction. Such a passage temporality conflates vanities and quarrels (politics) with time.

This obstinate belief that the past is closed and finalized and therefore stands apart from the conditions through which it comes to be defined in the present provides a rationale for its organization; this organizing of the past relies on the removal of subsequent impurities, that is, the destruction of other pasts. Thus one past advances at the expense of others. The destruction of Old Gurna, for example, relegates vernacular architectures to oblivion and once Lethe lays complete claim to those things that hold the memory of these pasts they are, as Laurent Olivier, puts it "capped." Their very existence becomes unimaginable, and "archaeology, whose fundamental practice is that of producing "material facts," finds itself directly involved in this perversion of history and [is] contaminated by it" (Olivier 2011: 22–23) and thus runs the basis for modernist chronopolitics, which hinge on this discrepancy between self-representation and practice seen in the substitution of involvements with detachments.

There is, of course, another, less dramatic side to chronopolitics, which turns around questions of memory practice – what is remembered and how it is remembered – and which is tied to the intimacies and experiences of archaeology. Museum exhibitions, artifact displays, site reports, archives, catalogues, and site preservation; all these technologies and modes of

engagement with the artifacts and vestiges of the past involve choices that are made about what matters, and this is of consequence in terms of what and how we remember. Such choices are always located and never neutral. This question of emphasis is of central concern for many archaeologists, so too are the stories we tell, both big and small. Michael Shanks and Chris Tilley, for example, saw that process of placing past societies within predefined typological sequences for the purpose of comparison as the politicization of time (1992: 53–54). This was because the time of the past was homogenized to facilitate interchangeability in cultural evolutionary terms.

Another species of *chronopolitics* locates archaeological materials in a flattened time of event and subsumes archaeology to history. The "positivist fallacy" is the label given by Anthony Snodgrass to the act of equating what is archaeologically observable with what is historically significant, to the confusion of what becomes of the past with what was of importance to history (1987). The "Pompeii premise" was the name given by Lewis Binford to the assumption that material vestiges speak to the moment of their deposition (1981). Ontologically speaking, archaeology actually deals less with what ancient times were like than with what becomes of what was (Olsen et al. 2012; Shanks 2012), which is always caught in a perpetual process of transformation. Formational and taphonomic processes (Schiffer 1987), nonlinear dynamics (McGlade 1999), and time perspectivism (the latter refers to Geoff Bailey's (2007) notion that different timescales relate to different features of behavior); all have played a role in a shift from the past as it was to a past ongoing in its transformations, transformations which played to the tune of disparate temporal rhythms (Lucas 2005). While all these debates were of consequence for how archaeology conceived of time, a less acknowledged aspect, to be sure, was how they revealed, whether directly or indirectly, the processes of selection, sorting, and serialization of things to be constitutive of particular temporalities. What is more, because much archaeological work privileges *chronos* by placing emphasis upon particular episodes, the pluritemporal mixture loses out.

Entropy and endurance are the bedfellows of time, witnessed in the intertwining of ephemerality and repetition, of perpetual perishing and incessant novelty, and of never-ending accumulation and duration. Thus, pasts endure as much as they transform. These are time's two arrows. To regard the past as gone, as irrecoverably behind us, not only denies the ways in which the past is still with us now, it also blinds us to those other pasts (things) that are rendered to oblivion (Olsen 2010). If there is no thing, then there can be no issue, no controversy, no politics, and no past. If there is no thing, then there are no grounds for the further production of time. Thus we continue to forget to serve particular interests. These acts are repeated time and again, from Gurna to Ayodhya and from Bamyan to Tara to Israel and Palestine.

Equally, accumulation and gathering lead to mixture and intertwining. Walk south along Via Appia through the Porta San Sebastiano in Rome, and you will dodge buses, lorries, and cars whose movements are modified by a third century AD gate and a road laid out in 312 BC. Every square meter of the eternal city is a polychronic ensemble, drawing simultaneously from various times. As such, it can be argued on ontological grounds that the past is not behind us, but it both gathers and co-emerges with us in the present, for we are wrapped up with it. Here we now encounter a broad movement from a time as successive, as a series of replacements to time as simultaneous, and as coextensive (this argument concerns the spatialization of time, which is the exact inverse of Virilio's (2000) temporalization of space). Seen from this angle, time is not an external parameter; the past is not a separate domain of reality. Time is a potency within and between things (Witmore 2015); the past is held as memories within things and is an outcome of their myriad interactions. Let us now consider chronopolitics in light of a wholesale reorientation of the temporal machinery so central to modernity.

To assume the past is gone accords the things of archaeology the position of intermediaries rather than full-blown mediators (Olsen et al. 2012). Chronopolitics, to reiterate, should not be seen as the exclusive domain of human *being*;

there is a self-realization in the ontogenesis of artifacts, monuments, remnants, vestiges, ruins, antiquities, and anything regarded as the material past. These things play just as much a role in their own formation as they contain human reality – indeed, these chronopolitics are more akin to what Bjørnar Olsen has described as unpredictable material trajectories that are "unrelated to human control and intervention" (2010: 110). Sites, monuments, artifacts, craft, and artworks, the things of the past, are either weakened or strengthened depending on a diverse array of interests – legislation, labels of World Heritage, hydraulic cement, walls around sites, neglect, or admission costs. When drawn into assemblages with archaeologists, community stakeholders, government or nongovernmental agencies, etc., things too can be said to have politics.

Controversies revolve around things, but these things are not always indifferent to those vested in their lives. Returning to the example from Gurna, one might ask, are the rock-cut voids tombs or the basements of contemporary houses? One cannot know in advance what the solid, indisputable, unquestionable reality *really is* like. And yet, this is precisely what the Egyptian government and the Luxor City Council did; they embraced the New Kingdom "tombs" as the indisputable common world. Cavalier in conflating the past, reality, and certainty, Gurna is realized as tombs, not as the basement of houses, which have now been removed. These practices confuse the outcomes with the starting points in order to serve exclusive interests. Reality is damned through a ruse, and time is controlled by powers that eradicate long-term memory and thousand-year-old traditions in the name of national heritage, scientific knowledge, and economic gain.

Even under the best conditions, the excavations of Old Gurna, as with anywhere, put forth one past to be experienced, felt, engaged in its presence, and others to be visualized, circulated, and read. And despite all the arduous care and meticulous detail, these things are evacuated of so much of their specificity. This is the tradeoff, which archaeologists readily accept. And yet for any material past to live on and to endure, it must be constantly worked at. Historical memory is a struggle. So which pasts are carried forward? Once again we turn on a question that was at the root of Nietzsche's essay on history. How do we know what should be remembered? This has always been a moving target in archaeology. No matter how neutral or democratic the aspirations, the constitution of things, sites, and the stories around them will always have a political life of their own (Casteñeda 1996).

For Nietzsche, history was always in service to life – so too is archaeology. Whereas the archaeologist was formerly a cultivator and curator of a detached past, she now enters onto the public stage as more of an active brewer of pasts coextensive within the present (Witmore 2013). This iterative, immanent, and kinetic experience is a remedy to living in the short term on the back of immediate reckonings by politics, economics, and mass media. Those things regarded as of the past are now pooled into an ever-present reservoir from which fresh alternatives may be crafted in the face of present dangers or perceived risks (Dawdy 2009; Gonzalez-Ruibal 2008; Shanks and Witmore 2010), from which new weapons may be fashioned against inequities and falsehoods. Thus we confront politics, following Randy McGuire (2008), as intervention and political action, from past struggles over labor rights in Colorado to exposing genocide in Argentina and Spain, Serbia, and Iraq. With Yosef Yerushalmi (1996: 117), we continue to wander whether or not the opposite of forgetting is justice. How much more rewarding and refreshing would it be to reopen *with* the material past rather than *against* it in defining a shared time – this is *chronopolitics* in the sense of living together peacefully with the pluritemporal; this is to draw from what has become of the past in another way, a way that remains in service to life.

Church Monuments Society

Kate Giles
Department of Archaeology, University of York, York, UK

Basic Information

The Church Monuments Society is a charity founded in 1979 as a focus for all those interested in the "appreciation, study and conservation" of church monuments in the UK and abroad "of all types and periods." The Society organises biennial symposia, study tours and excursions for its members. Its website (www.churchmonumentssociety.org) includes a series of useful resources for scholars and enthusiasts, including a brief history of monument types, county-by-county guides, an

illustrated glossary of forms, guide to symbolism and geology, and a bibliography. It also includes a section on newly-published works which are also reviewed regularly in its journal. The society can also be contacted c/o The Society of Antiquaries, Burlington House, Piccadilly, London W1V 0HS.

Major Impact

The Church Monuments Society is one of most well-respected, scholarly societies in the UK, with strong links to The Society for Medieval Archaeology, The British Archaeological Association and The Society of Antiquaries. Its major impact as a Society is evidenced by scholarly contributions its annual publication, *The Journal of The Church Monuments Society*. Since its first volume published in 1985, the journal has featured scholarly, peer-reviewed articles by the leading historians, art historians and archaeologists in the discipline, focused largely on the UK, and the period from the tenth to the nineteenth century. Articles include major overviews of the monumental brass and alabaster industries and workshops (Badham 1990), surveys of particular monument types, such as incised and cross slabs and burial vaults, particular iconographies, such as the Cadaver tomb (Oosterwijk 2005). Studies of individual monuments in both cathedrals (Harris 2010) and parish churches (Matich and Alexander 2010) provide important insights into the changing methodologies of monument studies. These often set individual studies in the much wider context of commemorative practice and Antiquarian scholarship.

In recent years, the journal has increasingly included international contributions from France, Germany, Italy, Spain, the Netherlands, Malta and Belize. It has also included a smaller number of studies of conservation works (Gittos et al. 1997), which feature more regularly in the twice-yearly Society newsletter and as the subject of its regional study tours. Abstracts of all papers in back issues are published online, whilst the website also features a useful searchable index of journal content.

Churchyard Archaeology

Aleksandra McClain
Department of Archaeology, University of York, York, UK

Brief Definition of the Topic

Churchyards, the external burial grounds associated with Christian places of worship, can

inform a wide range of social, economic, religious, and demographic issues which are fundamental to historical archaeology. Historic churchyards are explored through three primary methods: churchyard survey, excavation of the burials themselves, and recording the monuments that mark burials (Rodwell 2005: 161).

Churchyard survey and planning often stand on their own as methods, revealing complex relationships between the burial ground, monuments, buildings, topographic features, and the wider landscape (Mytum 2000: 137). Planning is also the first stage of excavation or monument recording, and geophysical survey can either help target excavation or serve as an alternative (Kerns-Nocerito 2002). Due to the complex stratigraphy and the ethical considerations of disturbing comparatively recent graves, churchyard excavations are generally limited to redundant churches or rescue situations (e.g., Brickley 2006; Mays et al. 2007), underscoring the importance of nondestructive survey as a research tool.

Monument recording provides essential information about memorial production and consumption, burial location, churchyard development, and local populations. However, it is also a vital tool of preservation, as historic graveyards lack statutory protection, and monuments are under constant threat of decay, movement, and loss. The recording, classification, and interpretation of churchyard monuments was pioneered in North American historical archaeology (e.g., Deetz and Dethlefson 1972), but the field has recently advanced substantially in both method and theory, such as in innovating and standardizing recording benchmarks (Mytum 2000, 2004), and in developing interpretations beyond status and economy, considering emotion, identity, and audience (Tarlow 1999).

Increasingly, projects integrating above- and below-ground archaeology have delivered the most noteworthy advancements in understanding historic burial practice (e.g., Mytum 2007; Tarlow 2011). Comprehensive non-destructive recording and survey is the standard methodology in modern churchyard archaeology, but where judicious excavation is feasible and ethically justifiable, or previously excavated data can be reassessed, a combination of the three approaches offers considerable potential.

Çilingiroğlu, Altan

Ece Birçek
Istanbul, Turkey

Basic Biographical Information

Altan Çilingiroğlu was born in Sürmene, Trabzon, in 1944. He studied archaeology at Istanbul University and received a state grant to complete his M.A. and Ph.D. at Manchester Victoria University in 1972. Following his return to Turkey in 1976, Dr. Çilingiroğlu assisted at Erzurum Atatürk University before he was promoted as assistant professor at Aegean University in 1982 and professor in 1988.

Major Accomplishments

As an undergraduate, Çilingiroğlu gained experience in significant excavations such as Can Hasan and Çavuştepe. After he was employed in the Aegean University, with the Division of Archaeology as a separate department in the faculty, he established the Protohistory and Near Eastern Archaeology Department. Together with management of excavations, he organized a series of symposiums, accredited internationally, in Iron Age content. In addition to this, he served on advisory committees of numerous institutions.

His expertise is mostly in ancient and prehistoric cultures of South Anatolia, Persia, Caucasus, and Urartian Kingdom. He conducted numerous seminars in Japan, Australia, Uzbekistan, and Germany and other countries. Çilingiroğlu has published more than 70 articles and 14 books about the Urartian Kingdom and its history, art, foreign policy, war, economics, beliefs, and Ulucak Hoyuk in İzmir.

Çilingiroğlu served as assistant dean from 1985 to 1989 and dean of the Faculty of Literature from 2000 to 2003. He is the former vice president and the member of the Turkish-American Association of Izmir, the principal member of the Turkish Institute of Archaeology, lifetime member of Archaeological Institute of the USA. Çilingiroğlu was the invited speaker for Australia's the University of Melbourne in 1989, Germany's University of Tubingen in 1991, Israel's Tel Aviv University in 1992, and University of Florence, Italy, in 1994. He was given an award by the Aydın Doğan Foundation for his contributions to archaeology in Turkey. Çilingiroğlu is still busy conducting excavations in settlements at Ayanis (Van) and Ulucak Mound (Izmir).

Citrus Fruits: Origins and Development

Alison Weisskopf and Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

Basic Species Information

Citrus fruits (*Citrus* spp. Rutaceae) are subtropical to tropical perennial fruit trees, producing juicy segmented fruits with thick rinds (Fig. 1). There are numerous named cultigens, with perhaps at least nine widely recognized, including mandarin or tangerine (*C. reticulata* Blanco), orange (*C. x sinensis* L. Osbeck), Seville, bitter or sour orange (*C. x aurantium* L.), the pomelo or shaddock (*C. maxima* Burm.), citron (*Citrus medica* Ferr), lime (*C. aurantifolia* Christm. Swingle), lemon (*C. x limon* L. Burm. F.), and grapefruit (*C. paradisi* Macfad.). In addition, makrut lime and leech lime or papeda are of widespread local importance in tropical Asia. However, as many as 300 species have been described, and this group presents taxonomic challenges due to the fact that these species readily hybridize, self-pollinate, and produce parthenocarpic fruit (asexually, with cloned seeds or no seeds). In addition, individual trees can present mutations on particular branches, which can then be reproduced readily by grafting. Many of the well-known, as well as lesser known, cultivar varieties are the result of a complex history of reticulate evolution. The main commercial citrus are derived from three basic species: *C medica* (citron, limes, and lemons), *C. reticulata* (oranges), and *C. maxima* (pomelo) (Scora 1975; Roose et al. 1995), in addition to *C. hystrix*. The complex taxonomic situation in citrus fruits warrants caution in interpreting historical, linguistic, or archaeological evidence.

Linnaeus first combined *Aurantium* (orange), *Citreum* (citron), and *Limon* (lemon) under the name *Citrus*. While Romans knew citrons and probably lemons, other taxa came to the Mediterranean only later. The name orange comes from a possible Dravic or Tamil root (*nraga*) via Sanskrit *nāranga* and Persian *Nārang* to Arabic *nārandj* to the fourteenth-century Spanish *naranja* and Portuguese *Laranjab* (Mabberly 2004). In English, "an naranj" turned into orange, and became associated with the color. Many of the common names for citrus cultivars are derived from Arabic reflecting the role the Muslims played in their introduction to Europe, following earlier diversification in India and tropical Asia (Ramon-Laca 2003).

Both the flowers and the fruit have economic value. The edible segments or carpels contain vesicles full of juice and are widely eaten or juiced. The flowers and seeds are the sources of neroli and petitgrain oils, the base of many perfumes. The skin or zest contains oils that have insecticidal value, and these have numerous medicinal applications. Citrus fruits are produced on large shrubs or small trees. They are susceptible to frost and sweetness cannot be achieved in cool areas. The color of the skin is dependent on the climate. In diurnal climates with a cool winter, the color changes, but in the tropics, the skin stays green.

Timing and Tracking Domestication

All these fruits are thought to have been domesticated somewhere in the area spanning from north eastern India to South China and Southeast Asia (Roose et al. 1995), but there is no firm evidence for precisely where or when (Fig. 2). Tanaka (1954) suggested a demarcation from the eastern Himalayas through Yunnan and north of Burma ending south of Hainan island, south of which he located the origins of the major citrus fruits, while minor related genera (*Poncirus* and *Fortunella*) might have had their origins to the north of this line, especially in southeast China. The origins of the citron (*C. medica*) may lie further west in South Asia, probably in the central Himalayan foothills, and the orange/mandarin (*C. aurantium*) group in Southernmost China/northern Indo-China. The pomelo is perhaps a later addition to the repertoire once sedentary cultivation and specialized arboriculture were established in mainland Southeast

Citrus Fruits: Origins and Development, Fig. 1 Representative fruits of *Citrus* cultivars representing the three main superspecies as well as *Citrus hystrix* and the kumquat *Fortunella japonica. Inset* shows typical seeds

Asia. The leech lime (*C. hystrix*) must be native to the Island Southeast Asia, but probably also the Malay Peninsula, and is suggested to have been translocated with early Austronesian expansions (Blench 2005).

Citrus fruits are poorly represented in the available archaeobotanical record. One challenge is in distinguishing the main superspecies or cultivars from seed morphology. It is also the case that seed finds are exceedingly rare in archaeobotanical

Citrus Fruits: Origins and Development, Fig. 2 Map of plausible centers of domestication of the original *Citrus* cultivars and the distribution of archaeobotanical evidence, sites numbered: *1*. Pompeii, *2*. Hala Sultan Tekke, *3*. Mon Claudianus and Mons Porphyrites, *4*. Quseir al-Qadim, *5*. Sanghol, *6*. Sanganakallu

assemblages. Citron cultivation is likely to have begun in the second millennium BC and perhaps began in the Gangetic basin or Himalayan foothills in the western portion of its range. The only early archaeobotanical seed evidence for *Citrus* fruits in South Asia comes from the Late Harappan (Baran Phase) site of Sanghol in Punjab, in the early second millennium BCE (Saraswat and Chanchala 1997). Wood charcoal may track its arrival in South India in the late second millennium BCE. Although reported as lemon, this level of identification is not clearly established from the reported seed material. Citron is more likely, as this is the closest to wild forms and was the first of the *Citrus* fruits to reach the west, where it is described in Hellenistic sources and presumably by the Persians, based on historical references. The early literary references are found in Sanskrit literature, which probably refer to citrons and/or lemons as well as some oranges in the early first millennium BCE (Asouti and Fuller 2008). Citrons are also known from Chinese sources, including Chi Han's flora of Southeast Asia from the fourth century CE (Simoons 1991: 201).

The arrival of citrus fruits in the Mediterranean and Europe is still poorly documented. A single archaeological report for citron comes from Late Bronze Age Cyprus, c. 1200 BCE, but has not been confirmed by direct dating (Zohary et al. 2012). Citrus seeds are said to have been found at the Sumerian ruins in Nippur by Kellerman in 1916, although their identification and date are uncertain (Webber et al. 1967). In addition to the citron (*Citrus medica*), lemons (*C. limon*) may also have been available during the Roman period in the Mediterranean. A single mineralized seed (possibly of lemon) was found at Pompeii dating to the early second century CE along with some pollen grains (Coubray et al. 2010). Paintings depicting Citrus trees in fruit have also been found at Pompeii and on Roman mosaics (Mabberly 2004). In Roman Egypt, desiccated citron seeds were found at Mons Porphyrites and Mons Claudianus dating to first and second centuries CE and seeds and rind at Roman period Quseir al-Qadim (Van der Veen 2011). Other Citrus cultivars probably did not arrive in the west until Islamic times (Watson 1983; Zohary et al. 2012). Rind from lime (*C.* cf. *aurantifolia*) has

been recovered from Islamic (eleventh–thirteenth century) Quseir al-Qadim (Van der Veen 2011). Citrus was brought to the New World by Columbus on his second voyage in 1493 (Scora 1975), and somewhere in the Caribbean, grapefruits evolved from a cross between a pomelo and an orange (Barret and Rodes 1976).

Clark, John Desmond

Martin Williams
University of Adelaide, Adelaide, SA, Australia

John Desmond Clark was born in London on 10 April 1916 and died on 14 February 2002 in Oakland, California. He was educated at Monkton Combe School and at the University of Cambridge, whence he graduated with First Class Honours in Archaeology and Anthropology in 1937. In 1938 he married Betty Cable Baume, whom he had met when she was studying modern languages at Cambridge. He was Curator and later Director of the Rhodes-Livingstone Museum in Northern Rhodesia (now Zambia) from 1937 until 1961 and built it into one of the finest museums of African ethnography and archaeology on the continent. During this time, he became well acquainted with all the leading figures in African archaeology and was instrumental in encouraging

regular professional interactions across Africa through the Pan-African Congresses on Prehistory held every four years in different countries in Africa, the third of which he organized in Livingstone in 1955 (Clark and Cole 1957).

During 1941–1946, he served in the British Army, initially as sergeant in the Seventh East African Field Ambulance Corps in Ethiopia, Somalia, and Madagascar. Even while on active service, his passion for prehistoric archaeology remained undiminished, and he collected artefacts wherever the vagaries of war conducted him, often under perilous conditions. Several pioneering papers were soon to appear in the South African Archaeological Bulletin describing various Late Stone Ages sites in Ethiopia.

During the war years, his wife Betty looked after the Museum in Livingstone, and she played a major personal and professional role throughout his life, helping with running the expeditions and commissariat, drawing artifacts, and assisting with the preparation of his scholarly manuscripts.

After officer training he became Civil Affairs Officer in the British Military Administration in Somalia until 1946, during which time he also seized every opportunity to carry out archaeological research. In 1948, he took a year's leave to be based at the University of Cambridge and was awarded a PhD degree in 1951 for his research on the prehistoric cultures of the Zambezi Valley, Ethiopia, and Somalia. Part of this material was incorporated into his first book on the *Prehistoric Cultures of the Horn of Africa* (Clark 1954). The Zambezi Valley work was to continue for many years and was published as three substantial volumes on *The Kalambo Falls Prehistoric Site* (Clark 1969, 1974, 2001).

In 1961 he became Professor of Anthropology at the University of California, Berkeley, where for 25 years he taught, spent up to three months each year excavating in Africa (Clark 1967, 1970, 1975, 1980; Clark and Bishop 1967) (and later in India and China), researched and published major monographs and scholarly papers until his notional retirement as Professor Emeritus in 1986. While at Berkeley, he developed a highly respected and very popular graduate program in African prehistory and paleoanthropology, assisted in later years by Glynn Isaac, who shared his profound love of Africa (Clark 2002). Many of the graduates from this program went on to occupy distinguished University positions throughout North America and were instrumental in deepening and extending Desmond Clark's pioneering work on African prehistory (Cooke et al. 1987).

Major Accomplishments

Professor Desmond Clark was by far the most eminent and productive scholar of African prehistory in the 20th century and had an unrivalled knowledge of African ethnography, archaeology and paleo-anthropology derived from 60 years of sustained fieldwork throughout that continent. He was author of over 300 research articles and author/editor of some 30 books and monographs. He carried out major excavations in Northern Rhodesia/Zambia (Kalambo Falls) (Clark 1969, 1974, 2001), Ethiopia (Gadeb, Middle Awash) (Clark et al. 1984), Somalia, South Africa (Clark 1959), Angola, Malawi, Tanzania, Niger (Adrar Bous) and Sudan (White Nile Valley) (Clark 1980), as well as Syria (Latamne), India (Son Valley), and China (Nihewan Basin). This work spanned some of the earliest evidence of human butchery practices and use of fire through the increasingly complex development of stone tools and associated hunting and foraging strategies to the causes and consequences of early food production. A measure of the esteem in which he was held by his peers was the invitation to dig for two seasons in central India with Professor G.R.Sharma and for several seasons in the Nihewan Basin in China with Professor Jia Lanpo.

An enduring attribute of all his work was the strong emphasis he placed upon interdisciplinary teamwork (Clark et al. 1984; Cooke et al. 1987; Clark 2002) and upon placing archaeological data into an ecological and landscape context (Clark 1967; Clark and Brandt 1984). He always took great pains to place his own research into a

wider environmental framework and was a past master at producing a scholarly synthesis (Clark 1970, 1975, 1980, 1982, 2001). One outstanding outcome arising from his network of professional friends and colleagues across Africa was the *Atlas of African Prehistory* (Clark 1967), which not only provided in easily accessible form distribution maps of all known prehistoric and fossil sites in Africa but had the added advantage that they could be superimposed upon maps showing geology, vegetation, and climate. Although superseded by new discoveries and easy access to satellite imagery, this atlas remains a useful introduction to African paleogeography.

His profound knowledge of African ethnography, much of it gained during long trips on foot across many parts of Africa, enabled him to weave his ethnographic insights into his interpretation of prehistoric practices and lifestyles (Clark 1980; Clark and Harris 1985). Desmond Clark also possessed a detailed knowledge of the entire temporal range of African prehistory, ranging from the Early Stone Age through to Iron Age. Another of his strengths was his willingness to make use of the latest technological breakthroughs in archaeological science, including new dating techniques and new methods of geochemical or paleoecologic analysis. Despite his formidable academic accomplishments and the many honors showered upon him, he remained humble, approachable, and helpful throughout his life. Many young archaeologists throughout the world have benefited from his encouragement and wise counsel.

Among the honors bestowed upon him were Commander of the Order of the British Empire (1960), Commandeur de l'Ordre national de Sénégal (1967), the Huxley Medal of the Royal Anthropological Institute, London (1974), the Gold Medal of the Society of Antiquaries, London (1985), the Berkeley Citation from the University of California (1985), the Gold Medal of the Archaeological Institute of America (1989), and Honorary Doctor of Science degrees from the University of Witwatersrand, Johannesburg (1985) and the University of Cape Town, South Africa (1985).

Basic Biographical Information

Professor Sir John Grahame Douglas Clark, C.B.E., F.B.A., M.A., Sc.D., Ph.D. (28 July 1907–12 September 1995), was an eminent British archaeologist. He was arguably one of the most influential prehistorians of the twentieth century, particularly within the economic and ecological fields of Mesolithic archaeology. He was born in Bromley, then part of the English county of Kent, and attended Marlborough College in the early years of his education. He arrived at Cambridge University in 1926 where he read history, archaeology, and anthropology at Peterhouse College. He completed his dissertation on the British Mesolithic in 1930 and was awarded his Ph.D. in 1933 (Rowley-Conwy 2001).

Clark received a 3-year Hugo de Balsham research fellowship in 1930. Two years later, he was awarded a Bye-Fellowship, elected a Fellow of the Society of Antiquaries of London (SAL), and became a founding member of the Fenland Research Committee (FRC), an organization that investigated the evolution of Quaternary geology at Fenland in Cambridgeshire, England. He was appointed Faculty Assistant Lecturer at Cambridge and Honorary Editor of the Proceedings of the Prehistoric Society in 1935. He was also the society's President between 1958 and 1962 (Rowley-Conwy 1999).

During the Second World War, Clark assisted the Royal Air Force in interpreting aerial photographs. He helped establish the Council for British Archaeology in 1944. He was made a Lecturer at Cambridge in 1946 and Disney Professor of Archaeology in 1952. He was a member of the Ancient Monuments Board from 1954 to 1977 and the Royal Commission on Historic Monuments from 1957 to 1969. He also held office as Vice-President of the Society of Antiquaries of London from 1959 to 1962 and served as a trustee of the British Museum from 1975 to 1980. He retired from the Disney Chair in 1974 but remained in Cambridge as the Master of Peterhouse from 1973 to 1980.

Major Accomplishments

With an extraordinary career spanning seven decades, Clark was an early pioneer of a more scientific and anthropological form of archaeological theory and research. His work foreshadowed some of the central ideas and aspects of the New Archaeology movement during the 1960s, and his influence left a profound impact on generations of archaeologists across the world.

At the age of 25, Clark published his Ph.D. dissertation as *The Mesolithic Age in Britain* (1932), in which he identified and defined distinct Mesolithic artifactual assemblages through the detailed study of their spatial and chronological distributions in Britain (Clark 1932). Between 1933 and 1940, he published eight articles and site reports for the FRC which combined archaeological stratigraphy and typology with palynology and environmental reconstruction, thereby redefining archaeology from a parochial study of typologies and surface finds towards excavations and a stratigraphic-geological approach that archaeologists hold as convention today (Smith 1994). His partnership with botanist Sir Harry Godwin in particular allowed him to correlate ecological data derived from pollen analyses with variations between assemblages and prehistoric periods.

Clark also extended the study of the extinct Mesolithic landscape into the European mainland with *The Mesolithic Settlement of Northern Europe* (1936). His insights into the cultural adaptation of prehistoric humans to their environment were further developed in *Archaeology and Society* (1939) and *Prehistoric England* (1940). This, in turn, led him to analyze the intertwining relationships between climatic and environmental variables and prehistoric economies in *Prehistoric Europe: The Economic Basis* (1952).

Clark is most renowned for his work at the Maglemosian lakeside settlement site of Star

Carr in Yorkshire, England. Published as *Excavations at Star Carr* (1954), it is still regarded as a seminal study of material culture and economy of a Mesolithic settlement within an ecological context. His work at Star Carr also produced a paper entitled *The Economic Approach to Prehistory* (1953), which contained a classic systems diagram depicting the complex interdependence of human culture with its environment that predated those of the New Archaeology by some 15 years (Rowley-Conwy 2002).

Clark's most important legacy lies perhaps with his students and protégés, many of whom became prominent scholars and archaeologists in their own rights, including Charles Higham, a leading authority of prehistoric Southeast Asia, and John Mulvaney, the "father of Australian archaeology." As Disney Professor, Clark was also responsible for employing Eric Higgs, the founder of the Cambridge Palaeoeconomy School, and David Clarke, who would become one of the principal proponents of the New Archaeology, thereby creating an exciting and vibrant learning environment for students at Cambridge University.

In recognition of his work and contributions in archaeology and prehistory, Clark was elected Fellow of the British Academy in 1951, appointed Commander of the Most Excellent Order of the British Empire in 1971, and knighted in 1992. He also received the SAL Gold Medal in 1978 and the Erasmus Prize of the Netherland's Praemium Erasmianum Foundation in 1990.

Classic Maya Collapse: An Alternative View

Anabel Ford
Exploring Solutions Past – The Maya Forest Alliance; ISBER/MesoAmerican Research Center, University of California, Santa Barbara, CA, USA
Department of Anthropology, Grand Valley State University, Allendale, MI, USA

Introduction to the Maya Collapse

The standard narrative of the Maya civilization is that they overpopulated their landscape and, to feed their populace, they had to expand their

agricultural fields, causing deforestation, erosion, and their demise. It is proposed that the land use practices of the Maya brought them over the tipping point, undermining their prosperity and resulting in the breakdown of their civilization (Diamond 2005; Webster 2002). Related conditions that are proposed to have exacerbated the inevitability of collapse prominently include drought in addition to epidemics, interruption of trade, and invasions that overtaxed the population's relationship to their landscape (Webster 2002). It is a popular notion that they disappeared.

Not until the nineteenth century was there general notice of the ancient remains of past glory, beginning with Stephens and Catherwood's masterful account and folios telling of towering temples and remarkable carvings deep in the Central American forest (Stephens 1963). Since the living population of the Maya area were deemed unsophisticated, they were disassociated from the extraordinary relics encountered in the forests. Subsequent adventurers and photographers trekked over the area and propagated the myth of discovery. By the time these travelers were encountering the ancient Maya civic centers (Fig. 1), the radical social impacts of the conquest, colonialism, and degradation had nearly completely divorced the indigenous Maya from their own past. Ecological imperialism has consigned their land use adaptations as inappropriate and primitive.

As in other parts of the world, ethnographic analogy is a key to the past: the historical land use recognized in the area relates to contemporary land use. Yet the sophistication of the Maya milpa forest garden that cycles from forest to field and transforms fields to forests is too often ignored by scholars of the ancient Maya. The fact that the Maya forest is replete with useful plants (Balick and Arvigo 2015) that serve for food, spice, fiber, medicine, construction, ornamentation, and other needs for daily life has been disregarded. As a result, the Maya understanding of the cyclical quality of the landscape and the seasonal qualities of the land use, knowledge of the forest products, comprehension of medicinal qualities of plants, and skill in maneuvering and managing in the Maya forest have barely been chronicled. Maya ecological appreciation reaches back millennia into the deep past of the Maya and underpins the development of the ancient Maya (Ford and Nigh 2015).

Flourishing at the time of the vicious Spanish conquest, the fields of the Maya were pillaged, construction materials plundered, and lives abused, all without consideration for the importance of Maya understandings of how to live with and manage large populations in the forest (Jones 1998). Life across the past millennia of the Maya civilization underwent changes in the context of the forest. With the conquest, all this would be disregarded despite it having served the Maya well.

Prejudices That Underpin the Narrative

At the crux of the problem, understanding the nature of the ancient Maya is the imposition of the Eurocentric view where arable means cultivable when it actually means plowable. Yet, the Maya used no plow. The cultivable landscape of the Maya flourished in the shallow friable soils of the limestone uplands, avoiding deep clayey soils that the conventional Western agricultural systems deem cultivable. Maya development depended on hand cultivation using labor, knowledge, and skill to increase the productive yield. It was not more fields, but more skill and labor in the field that produced greater yields (Ford and Clarke 2019). For the civilization to thrive, the Maya had to cultivate their landscape not only for crops but for all the necessities of daily life, including materials for construction and utensils, fibers and spices, resources for food production, and habitat for hunted animals. The Maya landscape was a cycle of varied forest habitats and productive fields that sustained everyday life. This tradition was unfamiliar to the Western eye and was literally overlooked.

The collapse comes to us based on the "discovery" of ancient monuments in the jungles of the Maya forests of lowland southern Mesoamerica. Despite the remarkable historic reports of the Maya at the time of the conquest of the 1500s

Classic Maya Collapse: An Alternative View, Fig. 1 Maya area with important centers noted

(see Jones 1998), there was the impression that the Maya were following untenable agricultural traditions that could not support but a few people. Evidence shows that the Maya continued to build and maintain centers, albeit smaller than the Classic predecessors, into the Postclassic after 1000CE and up to the brutal conquest. We know from historic records that they had astronomers who tracked the visible celestial bodies, that they wrote books of literature and science, and that they supported their populations with a cyclical agricultural system based on a multitude of crops dominated by maize (Terán and Rasmussen 1995).

From the Spanish documents, we learn that there was a great effort to consolidate populations, the standard economic policy of "reducción," to bring together settlements dispersed in their agricultural fields and orchards in far-flung locations around civic centers (Farriss 1984; Schwartz 1990). Huge efforts were made to impose Spanish standards on the Maya. In fact, Medel, the first governor of the Yucatan, misunderstanding the critical value of Maya land use, felt so uncomfortable with the way the Maya interacted with their landscape; he issued an ordinance in 1552 banning trees and field crops in the towns (Roys 1931: 157), ordering that "...they should not sow any milpas [fields] within the town that they construct houses close to one another [as the Spanish], that all shall be clean, without sown land or groves; and if there were any, *they should be burned*" (after Roys 1931, emphasis mine).

The Spanish did not comprehend the Maya landscape and did not see the forests as managed for their own utility. This fundamental miscalculation of the importance of Maya interaction with their landscape has persisted to this day. Permanent infields were part of homes in the principal urban locations as revealed in Medel's ordinance, while secondary houses were dispersed out of reach in diverse field areas as part of the traditional annual land use cycle (Ford and Nigh 2015). These are likely areas to which they escaped when hard pressed, as in the time of the collapse or under colonial rule. Because the sophistication of Maya land use has been ignored, misconceptions concerning the foundations of the Maya collapse have persisted.

Spanish avarice was at the foreground and relied on the prosperity encountered at the time of the conquest. Local landscapes were despoiled, ransacked, and ill-treated without recognition of the importance of local time-honored customs. The Spaniards were concerned with support in the short term; there was no concern for the long term, a strategy upon which the Maya civilization had depended. While the Maya civilization underwent transformations based on climate changes and on political-economic shifts, the cities and towns that the Spanish encountered in the beginning of the sixteenth century were based on the same principles of agriculture that sustained the Classic period before 1000CE (Terán and Rasmussen 1995).

The Exalted and Invisible Maya

The accounts of towering temples lost in the forest of Central America by the nineteenth-century explorers drew attention to the ancient civilization that once ruled over the tropical lands. But even with this attention, the indigenous peoples who lived around these centers and were speaking a local tongue were positioned as imposters, devolved relics that could not have built these impressive architectural wonders. The Maya had disappeared and no one acknowledged that they were talking to them. At the same time, their association with the ancient centers was eschewed, while their language, botany, and ways of life were the subject of much attention. Links were finally acknowledged as the hieroglyphic texts were studied and found to relate to the modern Mayan language (Coe 2005), but somehow, this link did not extend to incorporate their knowledge of the landscape and agriculture.

Even though the historical Maya land use must share common ground with contemporary Maya land use, this evident connection has been set aside. This is hard to conceptualize when one understands the fact that the Maya forest is replete with useful plants (Balick and Arvigo 2015). We now know that Maya ecological knowledge has roots back generations, centuries, and millennia as successful adaptations accounting for its existence today. The ecological thesis of complete agricultural failure that dominates scholarship on the Classic Maya collapse cannot be easily reconciled with the resilient skill and knowledge of existing traditional Maya forest gardeners.

Historical Perspectives of the Maya

From the outset, the Spanish conquerors were confounded by the floral diversity faced in the

Maya forest. By their own accounts, they focused on what appeared familiar: any field with crops, houses with rooms, water for transport, and resources for accounting. Their thirst for precious metals drove their expeditions, and their needs to feed horses and provision armies propelled short-term objectives.

The first Spanish incursions into the Maya heartland, initiated by Hernan Cortes in 1524 (Jones 1998), culminated with Ursua's conquest of the last Maya kingdom 1697. The expeditions followed indigenous maps, but the Europeans were confused by the narrow trails and frustrated with the lack of roads, unable to secure guides, and unconscious of the fear they spread (Farriss 1992; Jones 1998).

Unfamiliar with the Maya forest landscape and surroundings, and not appreciating the value in all they passed, they attempted to follow trails intended to be traversed on foot (Hassig 1985). Hardly known for their cultural relativism (see Roys 1931), the Spaniards perceived the landscape of the Maya forests as inhospitable and uninhabitable. Based on Cortes' Fifth Letter and Bernal Diaz's account, they struggled in this new world, adequately, not generously, provisioned by communities whose residents regularly fled at the army's approach. Terrorizing the countryside, the Spaniards were oblivious to the value of the cacao orchards they noted or the foods they garnered from the complex poly-cropped milpa infields and outfields as well as the significance of directed regrowth of economically important plants. The impression given in these early accounts misrepresented the presence of the Maya, and the later explorers reinforced this impression with the romantic descriptions of lost cities with no thought given to how they once thrived in these areas.

A Look at Population Size and Distribution

Population density and distribution are a critical component of the collapse equation. Estimates of densities of 500–1,000 persons/km^2 are exceedingly high, matching densities found in Taiwan and Bangladesh today. A revision of population estimates is critical to understanding land use of the Maya civilization. We have developed population densities for the representative El Pilar area based on grounded settlement surveys and a predictive model (Ford et al. 2009; Ford and Clarke 2019). These estimates for the El Pilar area of 140 persons/km^2 are in line with geographers' views of the Late Classic potentials (Turner 1990).

Far from a seething sea of humanity, at the height of the Classic period, settlements were concentrated in the well-drained uplands, avoiding the wetlands that make up an estimated 40% of the region (Dunning et al. 2002). Settlement impacts on the landscape varied according to settlement densities, as can be seen in the El Pilar example (Ford and Clarke 2019: 169). The greater the settlement and population, the greater the impacts. Estimated population density has an average of 140 persons/km^2 and varies up to 390 persons/km^2, with 38% of the area in unoccupied wetlands.

How do the estimates for the Maya of El Pilar compare with estimates in the ancient world? Boserup, for example, estimates that the Ming Dynasty China in 1500CE had an estimated population of only 64 persons/km^2 (1981: 11). This estimate is for a civilization supporting a standing army and navy, the ability to consolidate the Great Wall, and with major firepower and far-reaching tribute relations in a region substantially larger than that of the Maya. Pre-modern Edo Japan in 1750CE, under the centralized rule of the Tokugawa shoguns, in Boserup's estimates, had a population density of 128 persons/km^2. The average densities offered by Boserup are for a similar patchwork landscape of full, empty, and medium-intensity occupation for the preindustrial agrarian civilization.

The population estimates for El Pilar (Table 1) are somewhat greater than Boserup's examples of civilizations but are in line with geographic projections for the Maya area (Turner 1990). Recent research with Lidar for the central Maya lowlands (Canuto et al. 2018) found similar settlement densities for their large regional coverage in the Petén of Guatemala. Analyses of

Classic Maya Collapse: An Alternative View, Table 1 El Pilar landscape and estimated population distribution based on Late Classic settlement data

Geographic landscape	Area (km^2)	Late Classic residential unit estimate	Population density	Percent population (%)	Percent area (%)
Wetlands	485	0	0	0	38
Transitional	319	7,156	125	22	25
Uplands	225	7,643	190	23	18
Well-drained uplands	256	17,808	390	55	20
Total	1,284	32,607	142	100	100

these coverages produce reasonable estimates of 80–120 people/km^2, which extrapolate to population estimates of 7–11 million people across the 95,000 km^2 of the central Maya lowlands (Canuto et al. 2018).

Whatever the estimates, large or small, the impact of human settlement and population distribution is significant and cannot be underestimated. Humans are capable of making their mark, even when minimal infrastructure is used; and the Maya had significant infrastructure. For the Maya, we have foundations of small perishable structures and large temples and plazas. Land use would be most intensive where settlements and population densities were the highest. With 55% of the population in 20% of the area (Table 1), there would be little land to exploit for agriculture and forest products. Land would be more available where lower settlement densities and more extensive land were available for agriculture and forest products. Land use, however, had to provide for all the household needs: vegetables and meat, spices and fruit, fiber and utensils, as well as building materials and roofing. We know they were successful; evidence is found in major centers covering many hectares and numerous domestic sites near and far from the centers (Canuto et al. 2018; Ford and Clarke 2019). How they accomplished that success bears on our understanding of the nature of the Classic Maya collapse.

It is true that a higher population will exert greater demands on the landscape. This is the basis of the hypothesized overshoot that assumes there is a fixed carrying capacity for production in the Maya forest. This is, however, based on the assumption that intensifying land use and cultivation lowers agricultural yields and leads to environmental degradation (Webster 2002: 328–329). This would be the case in a Malthusian world where fields reduce the forest, but the Maya relied on the forest just as much as the fields. Both were part of the same cultivation process for the Maya in the milpa forest garden cycle (Ford and Nigh 2015). Any open field is eventually cycled into a utilitarian forest. Since the forest and fields are merely different phases of the same cycle, it is greater skill, knowledge, and labor invested that will increase agricultural yields (Ford and Nigh 2015: 41–76). Yields increased with labor and skill will not be compromising the extent of forested land cover (see Ford and Clarke 2019); the milpa forest garden cycle provides for horizontal and vertical diversity that ensures that land resources are adequately managed for maintaining fertility, conserving water, inhibiting erosion, sustaining biodiversity, and nurturing people.

Land Cover Interpretations

The narrative of the collapse positions the Maya need for agricultural crops as the basis of deforestation. This narrow view of the landscape's potential for food production does not take into account the varied needs of the Maya for materials derived from both forests and fields nor does the position have an appreciation for the cyclical nature of land use embedded in the milpa forest garden cycle. Simplistic views of forest and field do not account for the nature of the cycle where humans intervene, interact, and encourage natural processes (Conklin 1957).

The ancient Maya were an agrarian civilization. Their success was built upon care and manipulation of their landscape to fulfill basic needs for food and shelter for the few elite managers and multitude of farmers. Thus, to understand the collapse, we need to understand the conditions that led to the rise of the Maya civilization. It is the uncertainties of ecological change that propelled the development of the Maya, and it was stability that generated the vigorous growth of the political economy.

The ebbs and flows of the development of the Maya civilization across time provide the broad setting from which to understand changes in the landscape and climate. Climate changes in the present Holocene epoch were marked by significant temperature and precipitation events reflected in the paleoecological data (Fig. 2). A major change around 8,000 years ago was that from cool arid to warm humid, initializing the tropical characteristics of the lowlands today.

The following 4,000 years represented a relatively stable warm wet period in lowland Mesoamerican, known worldwide as the Holocene Thermal Maximum from 8,000 to 4,000 years ago. This period gave rise to the Archaic mobile horticulturalists in Mesoamerica and the Maya area. The developments that would evolve to support the agrarian Maya civilization were predicated on the early mobile horticulturalists' adaptation to the relatively high precipitation conditions of the tropical rainforest.

The end of the Holocene Thermal Maximum was registered around the world by significant climatic disruptions, and in the Maya area, this led to an extended 2,000-year period of climate chaos. When the mobile horticulturalists were challenged with the advent of inconsistent precipitation that began about 4,000 years ago, permanent settlements emerged in the well-drained areas across the Maya region. The trajectory of centralization coincides with some of the greatest and most chaotic extremes in precipitation (Fig. 2). The early formative or Preclassic developments portend the rise of the Maya civilization.

It is the uncertainties of ecological change in the Early and Middle Preclassic periods that appear to have propelled the development of the

Classic Maya Collapse: An Alternative View, Fig. 2 Summary of reported pollen proportions and precipitation as measured by trace titanium for the Maya area over 12,000 Years

Maya civilization with the buildings that were constructed to impress. Paleoclimatic data gathered from lakes of the Petén in the local Maya area, and connected with regional data from the Cariaco north of Venezuela, synchronize the emergent civic centers of the Maya to the time of unpredictable precipitation, rising and falling in rapid succession within the lifespan of a generation and across many centuries (Fig. 2).

As the volatile period of climate chaos attenuated around 2,000 years ago, precipitation trends became more predictable, if not drier. Precipitation stability in the Maya area by the end of the Late Preclassic marks the dawn of Classic Maya civilization. The Classic period, dating 250–900 CE, was a time of relative climate stability that persisted across the first millennia of our current era. This period corresponds to the rise of the trademarks of the Maya civilization with the erection of carved and dated stela commemorating of leadership and referring to regional alliances. All this was to come to an end by 1000CE. What does rainfall have to do with it?

Farmers in ancient Mesoamerica and specifically the Maya area relied on rainfall for their farming. Annual precipitations in the central Maya lowlands are relatively high, averaging c. 2,000 mm per year. Consequently, there has been a focus on annual changes in precipitation, on droughts, and on the role of rain in the productive yields of the ancient Maya. Rainfall will always present problems for the farmer, but it is not the annual rainfall that is an issue; it is the delivery across the year. Too little rain, or drought, when planting and too much rain, or deluge, near harvests have equally devastating results. It is the timeframe around the delivery of the rain that matters most for Maya farmers. So, yearly rainfall will not reflect the challenges on the landscape.

Collective water management would have been a major concern and a natural source of community centralization in times of scarcity, typically over the annual dry season, the *Yax K'in*, that today is traditionally predicted for March and April. This is a major reason for conserving land cover and shade that helps to retain humidity in dry periods. We need to remember, as well, that there are two wet seasons: the Chaak Ik' beginning in May to June and the Ik'al Ixpelon beginning in October to November. Thus, there are several planting periods over an annual cycle that can be impacted by rainfall. The rains of Chaak Ik' come from the east with thunder and hurricanes, and the rains of Ik'al Ixpelon come from the north associated with the winter storms of North America. No simple drought can account for all these dimensions, and even in a year of low rainfall, if it comes predictably, yields will be maintained.

As rainfall changes brought challenges for the of the earliest Maya, their development in the context of the tropical forested woodlands influenced their adaptations to growth. A study of the paleoecological chronology has been a significant source of support for the proposition of environmental impacts of the Maya. This is substantiated by the pollen data (Fig. 2) that feature the proportional abundance of wind pollen in lake core sediments. Wind pollination strategies, or syndromes, typically ones that make you sneeze, are a minority of plant pollen strategies that are dominated by animal pollination, e.g., birds, bees, and bats. This is especially true for tropical forest where only 2% of the plants rely on wind. Forests present many obstacles for wind movement and to successfully pollinate its designated object. Yet wind pollen dominates the record of lakes; we must balance the important, but restricted, environmental indicators that are provided by these data.

The assessment of the pollen data has been relied upon to back the proposal of Maya deforestation. The proof rests on evidence of the windborne pollen, a minority of pollen of the forest, that makes it to the water bodies. Dramatic changes in pollen are legitimately taken as valid and significant environmental indicators. Climate change from cool dry to warm wet c. 8,000 years ago marks a worldwide warming trend recognized from the Pleistocene to the Holocene. Human presence, though evident, was not yet strong. Later, after c. 4,000 years, changes are taken as the impact of Maya land use. This relies on the focus on the *Brosimum*-type pollen, referred to as Ramon and used as an indicator, or proxy, of

forest cover; but what does this proxy for forest actually tell us?

Using the rise of the tropical warm wet conditions of the Holocene Thermal Maximum, the record of the proportional dominance of *Brosimum*-type tree pollen has been relied upon to track the emergence of the forest. Since the rise of *Brosimum* is accepted to signal the expansion of the tropical forest, it has been used as *the proxy* for the forest per se. Its rise and fall have been assumed to reflect the expansion and contraction of the forest. Thus, the decrease of *Brosimum*-type pollen is the basis of the argument for deforestation. How is this justified?

When *Brosimum*-type pollen was depressed, there is an increase of "disturbance" pollen supporting an interpretation that the landscape changed from one of forest to one of human interference, with a negative connotation. This change has been interpreted as a shift from forest to "savanna" (Webster 2002: 255–257). This implies that the early dominance of forests gave way to grasses. Yet a careful examination of the data shows that the situation is far more complex. At the drop in *Brosimum*-type pollen, it is *not* grasses that are dominant, but forbs, leafy wind-pollinated annuals and perennials (Fig. 2) that proliferate in the open and secondary succession areas. These forbs are exactly what one would expect with a vibrant milpa forest garden cycle of open fields, directed stage of building perennials, and closed canopy mature utilitarian forest. Far from grassland savanna with few trees, the landscape evident in the pollen chronology is not one of deforestation but of much variety and diversity in land cover. This is exactly what the contemporary Maya use to curb erosion, moderate evaporation, conserve soil, and maintain a healthy environment.

The ethnographic data on the agroforestry practices of traditional Maya suggests that they managed the natural cycle to meet the agricultural and product needs (Terán and Rasmussen 1995; see Conklin 1957), and instead of "shifting" fields, they were building perennial forest gardens based on a patchwork of fields. Open fields, gaps in the forest, would increase the opportunity of "disturbance" plants that include many intentional and useful varieties represented on the landscape (Ford and Clarke 2019: 173–174; Ford and Nigh 2015: 148–149). In a hypothesized 20-year cycle, 15% of the landscape would be in milpa fields, and 18% would be in building perennials. Both fields and early perennials would have sufficient sun to contribute to annual and perennial shrubs that are defined as "disturbance" pollen. To complete the cycle, the field transforms into shaded mature perennials covering another 18% of the landscape. The total land use involved with the field to forest cycle would account for half the total available land area, leaving the remaining half in managed mature forests.

Revisiting the rise and fall of *Brosimum* in the forest, a multifaceted set of conditions emerge. The early rise of *Brosimum* in the region 8,000 years ago was a climate signal of the aggressive pioneering *Brosimum*, registered by its pollen, as it gained presence in the new warm tropical world. Its initial drop is likely another climate signal related to the stresses of coincident precipitation chaos around 4,000 years ago (Ford and Nigh 2014). At its nadir, corresponding to the rise and growth of the Classic Maya civilization, Ramon's proportional representation is clearly related to the impact of the Maya on the forest. But this is not likely deforestation; rather it is the opening field gaps that encourage the proliferation of wind-pollinated forbs and the preference for a diversity of useful trees known in the Maya forest today (Ford and Nigh 2015, p. 57), including *Brosimum*. In fact, carbonized remains in Classic Maya middens show plant diversity comparable to the modern Maya forest (Thompson et al. 2015), where the woods are dominated by fruiting and hardwood trees pollinated by birds, bats, and bees not evident in the general pollen records of the lakes.

Brosimum as the proxy for the forest is not justified. First, this is only one genus of a very biodiverse forest (Mittermeier et al. 2000). Further, as one of the 20 dominant plants of the Maya forest, it is the only one that is wind pollinated (Ford and Nigh 2015: 86–93). Second, the period of depressed *Brosimum* pollen shows much diversity in plant species, predominantly among forbs, the annual and perennial shrubs

that have been classed as disturbance species that are a significant part of forest succession and are important in Maya ethnobotany (Balick and Arvigo 2015). Third, succession of annual and perennial forbs is known from forest gaps and perennial building phases of the landscape, characteristic of land use consistent with the milpa forest garden cycle. Fourth, the rise of *Brosimum* pollen after 1,000 years ago, used to argue the return of the forest, is best explained as the expansion of the vanguard pioneer *Brosimum* into the neglected infrastructure of the Maya centers, consistent with *Brosimum* species preference of well-drained broken limestone habitats (Lambert and Arnarson 1982). Finally, the presence of forbs in the pollen record persists until 500 years ago, corresponding to the Spanish conquest when the real collapse of the Maya population occurred.

Redefining the Maya Collapse

The Classic Maya collapse rests on the assumption of a mismatch between population and resources (Diamond 2005: 176). Settlements and populations will, certainly, impact the landscape, but in the case of the Classic Maya civilization, growth and development over 1,000 years should be acknowledged as a notable success. With revised population estimates within the range of 100–200 persons/km^2 (relatively high on a world scale), such as developed for the El Pilar area and put forward by Turner (1990), along with the use of Maya ethnographic analogy for land use, so well relied upon for persistence of language and the cosmology, we can envision a different story.

Deforestation, critical to the abandonment hypothesis of the collapse, is based on a misunderstanding of pollen signatures of the milpa cycle, its productivity, and a prejudiced interpretation of the botanical record. Archaeologists have misread the settlement patterns and discounted the value of ethnographic analogy. Agroecologists have demonstrated the value of traditional Maya land use strategies to conserve water, build fertility, inhibit erosion, manage land cover, and support the needs of people (Ford and Nigh 2015). Yet this has been ignored in favor of placing the milpa in the role of destructive, indiscriminate primitive farming and the relegation of traditional swidden to the pejorative of slash-and-burn. This misconception is founded on uncompromising ecological imperialism founded in colonial views of land use limited by Western conventions (Said 1993).

The fundamental common theme of the Maya collapse is the "abandonment" of the major civic centers and the desertion of the population. Yet abandonment is only one possibility. People were living in the region at the Spanish conquest. Something did change, and what we *do know* is that upkeep of major centers of the lowlands, particularly in the greater region around Tikal (Fig. 1), decreased and, ultimately with neglect, the infrastructure became unusable, giving rise to new and smaller centers that were encountered by the Spanish in the 1500s.

Based on archaeological chronology, this collapse took some centuries to play out, founded on the last of the dated monuments and the estimated end of the Terminal Classic after 1000CE. Some propose a more attenuated time frame (Webster 2002), accounting for social and political consequences. Such upheavals are not unique and can be seen in historic times when the Roman capital was moved to Constantinople and more modern times with the demise of Detroit infrastructure while other US cities continue to prosper. These are examples where political and economic decisions play a major role in the transformations.

There is an undeniable steady growth and development of settlements and civic centers over several millennia prior to 1000CE. This reflects significant and consistent investments in major constructions and the concomitant administration of the necessary maintenance. Maintenance is the key and the evidence of "collapse" of Classic Maya centers. This reflects mainly on the interruption of continuity; abandonment is only assumed, not proven. The Spanish found an educated administration and complex civic centers, books written to document celestial movements and political relations, and a populace hierarchically organized by elite administrators, analogous to the structure of the Classic period.

Centralization, the hallmark of the Maya civilization, with the temples, plazas, and palaces, emerges early on in the context of climatic chaos. Rather than provoking environmental havoc, political dimensions take precedence. When the chaotic precipitation prevailed, it was critical to secure and manage water; this condition called for control, but stability would ultimately challenge this control. In the time of precipitation stability, growth can be measured by the increasing size and complexity of Maya civic centers. Yet land use of the Maya civilization was centrifugal, depending on farmers spread out to farmlands around the centers.

The Maya collapse is more likely a process that was part of the art of not being governed. The settlement of the Maya historically involved a complex pattern of residences to meet the demands of the annual agriculture cycle. Primary houses were based in a centralized infield location and the secondary houses in peripheral outfield locations. These patterns impacted the landscape by developing a mosaic of accessible fields and stages of forest that has made the Maya forest a garden and among the most biodiverse places in the world today. This would mean that secondary residences were part of the surrounding area providing an alternative living space.

Around 900–1000CE, Maya society underwent significant change after an astonishing millennium of growth. Reasoning that neglect of architecture implies complete abandonment is a logical leap. There is little question that the major civic buildings became "white elephants" and that their upkeep was increasingly compromised. Maintenance requires dedicated labor, and this was clearly a major source of the collapse. Knowledge of the civic management in the Classic period (250–1000CE) is not clearly understood. The burden of work obligations, nevertheless, would certainly fall to the general population. It would seem that the elite overdrew on the capacity of the populace to meet their exuberant expectations. It is not ecological demise that initiated the so-called collapse, but a political one. The farmers continued to be involved in the milpa cycle wherever they could.

Hinged on caring for infrastructure, by 1000CE, the political elite were unable to meet their maintenance obligations, and the administration of labor toward public ends broke down. Faced with the political crises, the population at large did not meet demanding commitments. Ultimately, life was simplified, and populations continued to manage their forest gardens, slowly leaving the large public structures of the civic centers to the elements. After all, the Maya were thriving at the time of the Spanish conquest.

Classical (Greek) Archaeology

James Whitley
Mediterranean Archaeology, Cardiff University, Cardiff, UK

Introduction and Definition

Classical archaeology is often considered an archaeology apart. It is an archaeological tradition that has quite different priorities and interests than those of European prehistory of American "anthropological" archaeology. There are reasons for this sense of difference, that relate to classical archaeology's peculiar history (Alcock and Osborne 2007: 1–29).

Historical Background

The Beginnings of Classical (Greek) Archaeology

Classical Greek archaeology begins not in Greece but in Rome. From the Renaissance onward, rich Roman families such as the Borghese, Farnese,

and Medici began to investigate the numerous Roman-era ruins of the city of Rome and its environs. They did this with a view to collecting art, particularly sculpture. Earlier Roman writers, in particular the elder Pliny, had listed many of the sculptures to be found around Rome, often referred to as "ars" (art or craft in Latin). Sculptures so classified however, though found in Rome, were often the work of Greek artists/craftsmen, and sometimes had Greek inscriptions to go with them. Indeed, one can argue that the peculiarity of the Latin term "ars" is that it refers almost exclusively to sculpture and painting made not by Romans but by Greeks, and refers to work produced within a relatively narrow chronological range (circa 500–250 BCE). This local tradition of classical antiquarianism continued throughout the seventeenth century, by which time aristocrats from other European countries (such as the Earl of Arundel, whose collection of Greek sculpture forms the core collection of the Ashmolean museum in Oxford) had begun to join the game.

Classical archaeology proper, as a form of systematic study of antiquity, is however usually held to begin with J.J. Winckelmann, whose *Geschichte der Kunst der Altertums* [History of Art in Antiquity, 1764] is the first attempt to deal comprehensively with the material remains of Greece, Etruria, and Rome. Winckelmann's study remains primarily a study of objects, not contexts, and remained firmly centered in Rome. In addition to sculpture and painting, it involved the systematic treatment of architecture, gems, mosaics, coins, and "vases" (as painted pots with Greek inscriptions came to be called). It devised a pre-Darwinian evolutionary scheme for the development of Greek art, one where a style that is "straight and hard" is succeeded by another that is "grand and square"; this is turn is followed by a "beautiful and flowing" style that eventually falls from grace, and becomes imitative and decadent.

Winckelmman's evolutionary scheme, with is rhythm of rise and fall, is more influential than some archaeologists working in other traditions might acknowledge. I doubt, for example, if Mesoamerican archaeologists would have coined their threefold scheme of "Formative/pre-Classic," "Classic" and "Post-Classic" for the Maya civilization without the (possibly unconscious and unacknowledged) influence of classical archaeology in general and Winckelmann in particular. And Winckelmann's scheme (though not his terms) have proved remarkably tenacious. When western Europeans began collecting sculptures, not only from Italy but from Greece, at the beginning of the nineteenth century (with the acquisitions of the Parthenon Marbles/Elgin Marbles and the Bassai frieze by the British Museum and the Aphaia pediments by Munich's Glyptothek [sculpture museum]), they fitted their finds into Winckelmann's scheme. And when, from 1830, Greeks won their independence from the Ottoman Empire, they turned to German scholars (such as Ludwig Ross), who was steeped in Winckelmann, to organize their fledgling state archaeological service. Conscious of recent losses, the Greeks were determined that no more works of art (sculpture, vase painting) were to leave Greece for Western Europe. So, when in 1874, the newly founded German Archaeological Institute in Athens requested permission to excavate at the major panhellenic sanctuary site of Olympia (where the original Olympic Games were held), the Greek authorities accepted, on one condition: All the finds were to stay in Olympia itself (Marchand 1996).

Just as Winckelmann's is the first systematic exploration of Greek art, so the excavations at Olympia were the first major systematic excavation of a Greek site. As well as major works of sculpture (such as the Nike of Paionios of Mende, and the pedimental sculptures from the temple of Zeus), the German excavators (Adolf Furtwängler and Wilhelm Dörpfeld) also recorded, studied, and cataloged hundreds of minor finds. Though the excavators paid some attention to context, the finds were published by material and type (all bronze figurines, for example). Other foreign and Greek archaeologists were spurred on by the German example, the French beginning their "grand fouille" at the equally important panhellenic sanctuary of Delphi in 1892. Finds were now pouring in from numerous excavations. By 1889, the Greeks had constructed their own neoclassical National Archaeological Museum to house these new discoveries. But the museum is (or was until recently) adorned with copies of "Greek"

sculptures (the Apollo Belvedere, the Doryphoros of Polykleitos) that were not, in fact, to be found at all in Greece, but in Rome. It is a National museum that deferred to foreigner's ideas of what "Greek," "classical," and "art" should be. A nation-building project, deeply entangled with archaeological practice (Hamilakis 2007), and dedicated to restoring the glories of ancient Greece was equally indebted to a Roman concept that is not to be found at all in the literature of Homer, or in any of the Attic tragedians, comedians, or philosophers – namely art.

This German-inspired archaeology of objects is not however the only intellectual tradition within the archaeology of classical Greece. There is another, focused on topography, ethnography, and landscape, that has its origins in the tradition of travel writers, particularly active from 1800 to 1830. Figures such as William Gell, Edmund Dodwell, E.D. Clarke, and Captain William Martin Leake traveled around Greece, collecting finds, making observations about the identity of classical sites (compare Dodwell and Leake at the Argive Heraion) and often with an engraver or watercolorist in tow (Whitley 2001: 44–7). Observations about the Greek past were juxtaposed with observations about the then state of what is now Greece (then part of the Ottoman Empire). Some of these observations are simply derogatory; others had considerable ethnographic insight. After the British lost out in the late-nineteenth century scramble for classical sites to excavate, this tradition was renewed in the early twentieth century. The principal excavators of the Archaic and classical sanctuary site of Artemis Orthia, near Sparta, A.J.B. Wace and R.M. Dawkins, produced a site report that dealt with thousands of votive objects, after the example of Olympia. But they also had wider interests: Dawkins in the modern Greek language and Cretan prehistory, Wace in ancient topography, prehistory, and the ethnography of the nomads of Northern Greece. This practice of seeing ancient Greece through the lens of modern Greece continued in the work of J.D.S. Pendlebury on Crete, and later in the archaeological surveys that began in the 1960s. These large, multi-period fieldwalking surveys (such as the Boeotia survey led by Anthony Snodgrass and John Bintliff, or the Kythera Island Project led by Cyprian Broodbank and Vangelio Kiriatzi) owe much of their practice to the influence of Anglo-American "processual" archaeology in the 1960s and 1970s. But they also continue a tradition that goes back to the travelers of the early nineteenth century.

Classical archaeology in Greece has then not one, but two distinct intellectual traditions, with distinct affiliations. The older, German one is an archaeology of objects, and concentrates its attention on major sanctuary sites, where objects are still published by material and type. It focuses on periods that are clearly classical (that is the Archaic, classical, and Hellenistic periods, circa 800–30 BCE). The alternative, largely Anglophone tradition is not so much focused on objects and on the Greek landscape. It takes a more diachronic approach to the archaeology of Greece, and its interpretations are informed by quasi-ethnographic observations of contemporary Greece. Of course, one can find exceptions to this neat scheme: Dörpfeld famously trenched the whole of the southern plain of Lefkada in a vain search for Odysseus' palace, resulting in an exemplary piece of landscape study (see Snodgrass 1987: 18–24), and perhaps the most celebrated artifact specialist of all time was J.D. Beazley, who attributed thousands of Athenian black- and red-figure vases to particular painters (or hands). But Beazley (as he acknowledged) was working within a field dominated by German scholars; Dörpfeld's work was not followed up by any German scholar for at least half a century.

Key Issues and Current Debates

The Scope and Practice of Classical Greek Archaeology

What are the boundaries of the classical archaeology of Greece? Chronologically, classical archaeology is held to begin with the inception of the Iron Age around 1100 BCE, continuing through the Archaic (800–480), classical (479–323 BCE), and Hellenistic (322–30 BCE) periods. Once upon a time, Aegean Prehistory (or at least the Bronze Age) was considered a part of classical

Archaeology, but nowadays, most scholars draw a thick line at the fall of the Mycenaean palaces around 1200 BCE (the line being the one where Aegean prehistory ends and classical archaeology begins). The status of the Roman period in Greece is ambiguous – the Greek Archaeological Service defines "classical" as ending with the accession of the Roman Emperor Constantine, everything after that being considered "Byzantine." Geographically, classical Greek archaeology comprises everything within these chronological boundaries found within the modern Greek state; finds from "Greek colonies" in Sicily, Southern Italy, the Black Sea, Libya, and Egypt; finds from cities that once lay within the boundaries of the major Hellenistic kingdoms in Anatolia (e.g., Pergamon), Syria, Jordan, Israel/Palestine, Egypt, Iraq, Iran, Afghanistan (e.g., Ai Khanoum), and parts of Pakistan; and (more ambiguous this) finds which look Greek (such as Apulian red-figure pottery) but which have nothing, in an ethnic sense, to do with Greek speakers as such (see Carpenter 2009). Conversely, areas of the ancient world which, while full of Greek speakers, but which did not (before Hellenistic times) make much use of the Greek alphabet or have an obviously classical material culture, such as Cyprus, are also in an ambiguous position. In practice, the criteria usually applied are simply whether an item looks "Greek" in the eyes of museum professionals; and, from their point of view, red-figure (even if Apulian) is Greek, whereas Cypro-Geometric pottery from Kourion or Salamis on Cyprus is somehow slightly Oriental.

These ambiguous boundaries affect archaeological practice. Within Greece itself, the state Greek Archaeological Service is responsible for local museums, but concerns itself primarily with rescue (or salvage) excavations made in advance of development. So, for example, the widening of the railway line to the North of the city of Thebes has resulted in a full exploration of that city's North Cemetery. A perennial problem remains that of storing, let alone publishing, all the finds that turn up from such excavations. Summary reports from such studies appear annually in the *Archaiologikon Deltion*. Greek universities (seven of which have archaeology departments) also engage in research excavations. Foreign archaeologists are represented by the so-called archaeological schools (in order of foundation, French, German, American, British, Austrian, Italian, Swedish, Swiss, Belgian, Australian, Canadian, Dutch, Danish, Norwegian, Finnish, and Irish), which are allowed a maximum of three field projects (survey or excavation) per year, and three joint projects with the archaeological service (*synergasies)*. The vast amounts of information all these activities produce is summarized annually in "Archaeological Reports" (published by the British School) and "Chroniques des Fouilles en Grèce" (published by the French). Both of these publications are now (jointly) available online.

Outside Greece, Greek "classical" archaeology is practiced in museums and university departments. The (once) Great Powers of nineteenth- and twentieth-century Europe and America have built up great, imperial museums, such as the Louvre in Paris, the British Museum in London, the Pergamon museum in Berlin, and the Metropolitan Museum of Art in New York. At the heart of these museums, at their core, are collections of Greek and Roman material, in particular objects referred to as "Greek art," chiefly sculpture and painted pottery. Indeed, it is often in these museums that the major pieces of sculptural ornament of major Greek temples are to be found. Sometimes a particular museum manages to preserve the sculpture in its entirety, as at the Pergamon museum in Berlin; at others, various museums hold varying amounts of sculptural ornament. So the pediments, metopes, and frieze of the Parthenon are divided unequally between museums in London, Athens, Rome (Vatican), Paris, Palermo, and Copenhagen. But these museums also contain vast stores of unexhibited finds (which may not count as 'art') from earlier archaeological projects. Often, restudy of these finds yields new insights. So, for example, the finds from Flinders Petrie's excavations at the Greek "emporion" (trading town) of Naukratis in Egypt are now being comprehensively restudied by a team from the British Museum led by Alexandra Villing. The aim is not simply to

produce a database, but to reinterpret in the light of new questions and theoretical concerns, using new methods (such as the advances in ceramic petrology achieved at the Fitch Laboratory of the British School at Athens). Restudying Naukratis can tell us much about interactions between Greeks and Egyptians in the Iron Age, about ethnicity, and about the "connectivity" of the Mediterranean world in the Iron Age.

Equally, the actions of great museums are sometimes determined by their founding values. The Metropolitan Museum of Art in New York is pre-eminently an art museum. Unlike its neighbor, the American Museum of Natural History, on the other side of Central Park, objects in the museum are treated primarily as "works of art," that is, objects whose aesthetic value exists independent of any cultural, social, or historical context or interest, and are displayed as such (see Price 1989). The "object biography" of a Greek vase acquired by the museum in 1972 illustrates the point. This object was a late Archaic Athenian red-figured calyx krater potted by Euxitheos and painted by Euphronios, whose principal scene was two winged figures (Sleep and Death) taking away the body of the Trojan/Lykian hero Sarpedon (see *Iliad* 16. 476–507), killed by Patroklos. The justification for the acquisition of (and the price paid for) this vase was that it was a "work of art," in every sense comparable to woodcuts by Dürer or the painter of the Book of Hours (Watson and Todeschini 2006: x–xi). The seller was rather coy about its provenance, though there was a suggestion it might have been found in Beirut. Other scholars, who knew that other kraters painted by Euphronios had generally been found in Italy, with a large number coming from the Etruscan city of Caere (Cerveteri), were more suspicious. It later transpired that this vase too did indeed come from Cerverteri. It had been looted from an Etruscan tomb by *tombaroli* (tomb robbers), and broken in the process. It was moved via Switzerland and London to New York when (after being repaired) it appeared on the art market, and was then acquired by the Metropolitan Museum. After these facts came to light, it was subsequently returned to Italy, and is now to be found in the Villa Giulia in Rome.

There are two possible reactions to this story. One is, with James Cuno (2008) to lament that another of the prize specimens of one of the world's "universal" museums has been lost to the nationalist pressure of the Italian state, aided and abetted by UNESCO. This attitude was shared by a former Director of the Metropolitan Museum, who is on record as saying that all that is really significant about the Euphronios krater is "on the vase." I beg to differ. If we knew the precise context of this krater, if we knew what objects and persons were buried with it, and if we could determine their "object biographies," we would know a lot more about the Iron Age/Archaic Mediterranean world. We could begin to address such questions as: Why were the Etruscans so interested in Greek (particularly Athenian) painted pottery? Did they appreciate and understand the whole cycle of tales told about the Trojan War (especially relevant to the neighboring city of Caere, with its origin myth of Aineas, namely Rome)? Was this vase made for Italian consumers, or did it come to Caere "second hand"? This object, no less than the finds from Naukratis, is highly relevant to our understanding of Mediterranean connectivity (sensu Horden and Purcell 2000), and it is a pity that many museum curators and directors still do not seem to appreciate this simple point.

The point is perhaps easier to appreciate from a university's perspective. Archaeologists attached to universities, whether they are in departments of classics or art history (as is generally the case in the United States) or in departments of archaeology proper (as is the case in the United Kingdom), usually want to be involved in field projects, the only way in which to recover new information. Whether these projects are survey projects (involving fieldwalking) or excavation, the importance of locating finds in time and space, that is, in context, becomes second nature. It is also in universities that most of the debates about the nature of classical archaeology have taken place. Is classical archaeology just the archaeology of certain regions of the Mediterranean, whose methods and theories should differ little if at all from archaeology in general? What distinguishes classical archaeology from other archaeologies that deal

with historical periods (such as medieval archaeology, or that species of historical archaeology that deals with the colonial period in the Eastern United States)? There are several possible answers to these questions. As long ago as 1943, the distinguished (if classically educated) European prehistorian V. Gordon Childe argued strongly for the unity of archaeology, and suggested that the excavation and interpretation of classical houses at Olynthos in Northern Greece was no different in principle from the excavation and interpretation of the houses of the prehistoric (or "Pictish") village of Skara Brae in the Orkney islands (Childe 1943; see also Whitley 2001: 12–16). Both involved a considered approach to understanding domestic space, to defining the activities that took place in parts of the dwelling, and the importance of gender divisions within the household. Archaeologists who take a different view tend to emphasize one of two things: the unique standing of the classical Greek achievement, or the unique significance of its art.

These questions have gathered force and urgency as classical Greek archaeology has been affected by developments in other archaeologies. "New" or processual archaeology, as developed by anthropological archaeologists in North America or by prehistorians in Britain in the 1960s and 1970s, initially had little effect on the practice of classical archaeology. In the 1980s, however, a more scientific and quantitative classical archaeology began to emerge. Finds from sanctuaries that were once cataloged were now also counted, to reveal trends in depositional practices. These trends could be understood as processes, processes integral to the emergence of states [or at least *poleis*] in Archaic Greece (Snodgrass 1980). This processual and quantitative spirit informed the development of field survey during the 1980s, most especially in the Boeotia survey (see above). At about the same time, a number of French and German classical archaeologists had been applying structuralist approaches to the interpretation of images on sculpture and vases. These streams of thought come together in Francois de Polignac's *La Naissance de la cité grecque* (1984), which in some ways anticipated the "phenemenological" approaches that were to become fashionable in European prehistory after 1994. Social and contextual studies of Greek mortuary practices, and of the painted pottery found in graves, came to the fore by the end of the 1980s (Morris 1987; see also Whitley 2001: 55–7). This led to the expectation in some quarters (notably Shanks 1995) that classical archaeology would follow British prehistory in developing from a "traditional" through a "processual" and finally to a "post-processual" stage. This has not come to pass – traditional classical archaeologists have not been supplanted, but supplemented by other scholars with a range of theoretical interests, expressed with varying degrees of explicitness.

Classical Archaeology in Greece: Current Issues and Debates

The key practical debate relates to museums. Should the bulk of classical Greek material culture (and art) be held in "universal" museums (such as the British Museum), museums whose mission is to hold a representative part of the material remains of all civilizations? The argument for this is that greater intellectual and aesthetic insights will be gained through juxtaposing Greek and Roman with Assyrian and Phoenician (or even with ethnographic material from Polynesia) than will be gained if all material is simply held in the museums of nation states. Universal museums celebrate civilization as a whole, and act as an antidote for various nationalisms (in this case, Greek nationalism). Directors of these museums have certainly begun to make use of the rhetoric of object biography and of agency. But it has to be admitted that, as far as the Greek collections of the British Museum are concerned, the promise of the universal museum that makes arresting *comparisons* across time and space has yet to be realized. Trophies of captured Greek armor have not been juxtaposed with Congo nail fetishes, as "visible knot[s] which ties together an invisible skein of relations, fanning out into social space and social time" (Gell 1998: 62; cf. Whitley 2011). Moreover, the rhetoric of the "universal museum" glosses over the fact that such museums were, in origin, imperial museums. As one early twentieth-century British politician noted, the

British Museum's acquisition of major parts of the Mausoleum at Halikarnassos (one of the seven wonders of the ancient world) was aided by "a Company of Royal Engineers and Sappers, and a British man-of-war lying at a handy distance in a convenient bay" (Asquith 1900: 136–7).

The recent completion of the new Acropolis museum in Athens has brought these issues to the fore. This museum is explicitly designed to house, and reunite, all the fragments of the Parthenon now held in several parts of the world. As such, it is designed to advance the argument that the architectural decoration of the Parthenon must, first and foremost, be seen in *context* – and it is this, and not nationalism, that is the issue. But it has to be said that it makes this argument very poorly. For the new museum, pre-eminently, represents the ideology of the Greek political class. And, like the Greek political class, the museum is ultramodern on the outside, and ultraconservative on the inside. The plaster casts of the Parthenon frieze (taken from originals in the British Museum and the Louvre) are not painted, to give some idea of how the polychrome originals might have looked. In deference to an outdated neoclassical sensibility, they remain white – indeed, ultra-white, like teeth in advertisements for toothpaste. The Archaic votive sculptures from the Athenian Acropolis are not placed in context, or explained or displayed as votives, and linked to their inscriptions. They are not linked to debates about Archaic Athenian society. Instead, they are treated as individual works of art, that is, objects whose intrinsic aesthetic worth requires no contextualization (see again Price 1989).

Museums remain places where the impact of new ideas can often be seen. The new displays of Greek material at the Ashmolean museum in Oxford reflect, to some degree, the new interest in Mediterranean "connectivity" (Horden and Purcell 2000), and new debates about identity. "Greek" is no longer a self-evident category. The key debate in museums however remains the status of the objects displayed. Should Greek vases be seen as "artworks"? The new displays at the Ashmolean suggest not.

The debate on "Greek art" remains a lively one. On the one hand are scholars (such as myself) who, following Gell's (1998) recommendation of "methodological philistinism," see no reason to give sculpture and vase-painting special status. What is of interest is the agency of objects and the way they are entangled within social practices. So the importance of a *kore* with an inscribed base from the Athenian Acropolis is how its study contributes to debates about Athenian society, and whether that society was "aristocratic" (Duplouy 2006). Equally, the significance of the Nike of Paionios of Mende is not its aesthetic effect, but the way it negotiates the Scylla of *nike* and the Charybdis of *hybris* (Whitley 2011). On the other side are scholars such as Richard Neer, who insist that Greek sculpture can be understood in *aesthetic* terms, terms moreover which would have made sense to an ancient Greek (Neer 2010). This debate will run and run, as it goes to the heart of what classical archaeology is.

There are of course other major debates. One relates to identity and acculturation, and how processes such as the "Orientalizing" should be understood (Morris 2003). Another concerns the relationship between the various intellectual traditions that make up classical Archaeology – in particular, the German (Marchand 1996). There are developing connections between research themes. Both field survey and the debate about Mediterranean connectivity, for example, build on the work of the French historian Fernand Braudel, whose concept of the *longue durée* underpins the practice of diachronic, regional survey.

And yet, the skeptical prehistorian may ask, has classical archaeology in all this actually undergone anything like a paradigm shift? What has it contributed to archaeology as a whole? Some have answered the first of these questions in the affirmative (e.g., Snodgrass 1987, 2006: 78–104). As to the second, one could point to advances in field survey. But, in my view, the best example of a paradigm shift having taken place within classical archaeology, and of its wider (and beneficial) effects in the field of archaeology as a whole, is to be seen in the field of ceramic petrology. The establishment of the Fitch Laboratory at the British School at Athens in 1974 provided a place where scientists, trained

in the natural sciences, could work closely with archaeologists, whose background lay in the humanities. Through the vision of Hector Catling, and successive Fitch directors (Richard Jones, Ian Whitbread, and Vangelio Kiriatzi), C.P. Snow's "two cultures" could be bridged. Early expectations that the origin of painted pots could be determined by simple chemical tests proved only partially successful. It gradually became apparent that the production, distribution, and consumption of pottery, painted or coarse, involved a whole range of social as well as technological issues. Scientific advances (in the description of pottery fabrics, by Ian Whitbread) went hand-in-hand with discussion of the cultural dimensions of pottery production. The Fitch's methods combined field survey, ethnoarchaeological research into modern potters, archaeological experiments in replication of fabrics and various kinds of chemical and petrographic (thin section) analyses. The overall result is that archaeologists in Greece now approach pottery looking as much as the fabric (what it is made of, and how) as the surface decoration or shape. This is a genuine paradigm shift in the way we see pottery, and one which is having profound effects on other archaeologies.

Classical Greece, Archaeology of (c. 490–323 BCE)

Kathryn Topper
Department of Classics, University of Washington, Seattle, WA, USA

Introduction

The Classical period in Greece spans most of the fifth and fourth centuries BCE, an age that witnessed both the Persian and Peloponnesian wars, followed by the rise of Macedon and the conquest of Western and Central Asia by Alexander the Great. Athens is represented disproportionately in the scholarship on this era, particularly in studies of the fifth century. This situation is due in part to the reputation of fifth-century Athens as a cultural zenith in the ancient world, although the survival of important monumental architecture in Athens and the surrounding countryside – and particularly the buildings from the Periclean building program on the city's acropolis – has also contributed to the focus on that region. Classical Athens is thus sometimes treated as representative of most or all of Greece in this period, although this perception probably does not reflect the reality of the ancient situation. Some Greek states are known to have differed markedly from Athens in customs and material culture; the most dramatic example is Sparta, Athens' major political and cultural rival. Unfortunately, the material remains from Classical Sparta are relatively scant, and they seem not to reflect the importance of this state in antiquity (cf. *Thuc*. 1.10.2).

Definition

Scholars traditionally define the Greek Classical period as the years between the first Persian invasion in 490 BCE and the death of Alexander III of Macedon, or Alexander the Great, in 323 BCE. Because of the importance of these dates in political and military history, they provide convenient chronological bookends for the period, although it is important to recognize that they do not necessarily reflect the state of material culture at individual archaeological sites, which often show significant continuities with the Archaic or Hellenistic periods. Geographically, "Classical Greece" encompasses the mainland and surrounding islands, as well as the colonies in southern Italy and western Asia Minor. Despite certain differences in culture and political structures, Macedonia is often considered in conjunction with Greece in this period; this is especially true for the latter part of the fourth century, when Philip II brought the Greek *poleis* (city-states) under the control of Macedon, and indeed, the remains from Macedonian sites such as Pella and Vergina attest to familiarity with the religion, mythology, and language of the Greeks.

From its beginning, the archaeological study of Classical Greece has been closely tied to the study of its architecture and art (although it is important to note that the Greek language had no word that corresponds to our definition of "art"); consequently, these topics loom larger in the archaeological scholarship of this period and region than in scholarship focused on many other times and places. Painting (primarily on pottery) and sculpture (in both stone and bronze) constitute the majority of the art historical evidence from this period, and architectural evidence ranges from large public buildings in sanctuaries to the remains of houses at sites such as Olynthos. Epigraphy and numismatics, while subdisciplines of Classical studies in their own right, have contributed much to the archaeological study of the Classical Greek world; faunal, archaeobotanical, and osteological remains also add to our understanding of this period, although they have traditionally played a smaller role in the archaeology of Greece than in that of other reasons, in part because many important Greek sites were excavated before the use of scientific techniques in archaeological studies became common.

Historical Background

The beginning of the Classical period is marked by the invasion of Greece by Darius I in 490 BCE;

his army was repelled that summer in the famous battle of Marathon, but 10 years later, the Persians invaded again, this time under the command of Darius' son Xerxes. The Greek forces again managed to defeat the invaders, but not before the Athenian acropolis was sacked and burned, an event that would be memorialized in the midcentury rebuilding of the sanctuary there. Following the Persian invasions, the Greek states began contributing funds to the "Delian League," the modern name given to the coalition led by Athens to defend against future invasions. As a result of Athens' management of the treasury, the middle and later decades of the fifth century saw mounting tensions among the Greek states, which culminated in the so-called Peloponnesian War of 431–404 BCE. During this long and bloody conflict, two coalitions of city-states faced off under the leadership of Athens and Sparta; although Sparta proved victorious, historians and archaeologists know far less about that state than about Athens, which remained highly visible in the material and literary record despite never returning to its former strength. The early fourth century saw Sparta, Athens, and Thebes jockeying for power in the Aegean; by the middle of the century, Macedon, under the leadership of Philip II, had also become an important player, and in 338 Philip's forces defeated the Greeks at the battle of Chaeronea, bringing the Greek cities under Macedonian control. Upon Philip's assassination in 336, his son Alexander III (Alexander the Great) assumed command, and he quickly moved into Asia, conquering large parts of the continent before dying in Babylon in 323. His death traditionally marks the end of the Classical period, and the years that followed were characterized by fragmentation of his empire and struggles for political and cultural supremacy among his successors.

The major archaeological sites of the Classical period include sanctuaries, towns, cemeteries, city centers, houses, and the industrial district of Thorikos in Attica. The sanctuary site that has attracted the most attention from scholars is the acropolis in Athens (Hurwit 1999), which included a sanctuary of Athena, as well as smaller ones devoted to other gods. The Athenian acropolis had already been an important site for centuries when the Persians sacked it in the early fifth century BCE, and the midcentury Periclean rebuilding program there contributed temples such as the Parthenon and the Erechtheion that are considered iconic even today. On the slopes of the acropolis sat the theater of Dionysus, where many of the ancient Greek comedies and tragedies that survive today were originally performed.

Temples and theaters were both frequently associated with Greek sanctuaries, although neither was required; in fact, the only necessary features of a sanctuary were the *temenos* (the plot of land reserved for the god) and altar, and some could be quite simple. Two of the most important sanctuaries, those at Delphi and Olympia, continued to be developed in the Classical period, although both had their origins in earlier periods. Both sanctuaries were Panhellenic (open to all Greeks) and were sites of athletic competitions as well as other sacred activities; Delphi was also known as an important oracular site. Other sanctuaries that were embellished during the Classical period include those at Eleusis, Brauron, and Epidaurus; this last site was home to the cult of the healing god Asklepios, and excavations there have recovered surgical tools, sleeping quarters for the sick, inscriptions detailing divine cures, and a variety of votive offerings left by pilgrims.

In addition to the public, sacred architecture of sanctuaries, archaeologists have excavated a number of houses that offer insights into facets of Classical domestic life (Nevett 1999, 2010). The so-called "Vari house" in the Attic countryside preserved a threshing floor and terracotta beehives, although most evidence for domestic life in the Classical periods comes from more urban areas, most notably the town of Olynthos on the Chalcidice peninsula in northeastern Greece. This city, which was destroyed by Philip II in 348 BCE, was excavated by an American team in the 1930s and remains one of the most important sites for the study of Greek domestic architecture. Its orthogonal plan was typical of cities built in the Classical period, and it includes blocks of modest houses with somewhat repetitive – if not entirely uniform – floor plans. Unfortunately, Philip's forces destroyed all but the foundations of most of the

houses, so crucial information about the upper stories that are known to have existed has been lost. Nevertheless, the site has yielded some important finds, including hundreds of terracotta loom weights; several houses also preserve pebble mosaic decorations on the floors of the *androne*s, men's dining rooms where drinking parties called symposia were held.

The central square of a Greek city was called an *agora*, several of which have been found throughout the Greek world. The *agora* that has received the most attention in modern times is the one in Athens, which is still undergoing excavation and which received several embellishments in the Classical period (Camp 1986). Athens is also known in modern times for its large extramural cemetery, the Kerameikos, where burials date back to Submycenaean times. By the Classical period, many of the private funerary monuments were stelae marking burials that were organized in plots, although one area of the Kerameikos, the Demosion Sema (Public Tomb), held burials of those who had died in war (Camp 2001).

A good deal of sculpture and painting survives from Classical Greece, and this along with the evidence just discussed forms the bulk of the material traditionally studied by archaeologists focused on this period (Stewart 1990; Boardman 2001), although the overwhelming focus on these types of evidence has been justly criticized (Lapatin 2003). Both sculpture and painting present scholars with a variety of difficulties, which in many cases result from the circumstances under which each type of material has been preserved. Most freestanding sculpture of the period was cast in bronze or constructed of other perishable materials (such as gold and ivory) and was thereafter melted down or otherwise destroyed (Mattusch 1988, 1996). Consequently, most Classical bronze sculptures are known only from literary accounts and the so-called Roman "copies," both of which present problems that are discussed below. Those that do survive – such as the Piraeus bronzes or the famous Riace warriors – tend to come to us from shipwrecks or warehouses, so scholars are unable to study them in the physical contexts for which they were intended.

Most of the sculpture that survives from the fifth and fourth centuries is stone architectural sculpture, frequently from temples; sanctuaries at Athens, Olympia, Bassae, and elsewhere have been especially useful to scholars concerned with sculptural trends in this period (Stewart 1990). To the extent that it is possible to generalize about sculptural styles of the Classical period, one can detect a move away from the rigid forms of the Archaic period, as well as an increasing interest in volume and movement rather than linear detail, although it is important to note that stylistic development was not completely uniform throughout the Greek world.

As with sculpture, the study of Greek painting is hampered by loss of important material; in fact, with a few exceptions, Classical Greek monumental painting is known mainly from literary accounts. We do, however, have thousands of pieces of painted pottery from Greece in this period, the bulk of which was produced in Athens in the fifth century and South Italy in the fourth (Boardman 2001). These objects, which were created for activities ranging from the symposium to the funeral, have furnished scholars with a tremendous amount of information about the mythology of the Greeks; there are also many scenes that have traditionally been thought to show daily life in Athens in elsewhere, although this interpretation is increasingly acknowledged as suspect (Ferrari 2003).

A few monumental paintings survive from this period; the earliest are the frescoes in the Tomb of the Diver at Paestum in Italy, which seem to date to c. 480–470 BCE. These paintings, which show a symposium and a diver, are consistent both stylistically and iconographically with the vase paintings that were being produced in Athens at the time; such similarities lend some credibility to scholarly efforts to understand lost monumental paintings from the evidence of painted pottery (Holloway 2006). Fourth-century Macedonia has also yielded a handful of monumental paintings; several tombs in a late-century royal tumulus at Vergina bear painted decoration, and the themes (a mythological abduction and a hunt) have parallels in art from Athens and elsewhere (Andronikos 1984).

Key Issues/Current Debates

A number of current debates in Classical Greek archaeology involve questions about how to interpret the surviving visual evidence, although these questions have implications that extend well beyond art historical concerns. As noted above, most of the bronze sculpture from this period has been lost, and for many years scholars relied on a combination of literary texts (such as the *Natural History* of Pliny the Elder) and Roman statuary to reconstruct famous lost pieces; it was believed that Roman sculptors were interested in producing faithful stone replicas of earlier Greek bronzes. It is now understood that Roman sculptures cannot be reduced to a series of copies of earlier works (Ridgway 1984), but since the foundational histories of Greek sculpture were written at a time when the old assumptions were believed to be valid, the generally accepted history of sculptural styles and chronologies for the period will need to be updated. Closely tied to this issue is the question of how literary sources should be brought to bear on the interpretation of visual and other material evidence; although these sources frequently furnish archaeologists with indispensable information about the past, they also contain important nuances to which we have not always been sensitive.

How to interpret visual evidence is also a matter of concern for scholars who focus on painted pottery, particularly when it comes to images that have been traditionally classified as "scenes of daily life." These images have frequently been used to fill in gaps left by other forms of evidence, and our understanding of the ways in which Greek people in the Classical period ate, drank, worshipped, practiced athletics, had sex, and buried their dead depends to no small degree on the evidence of the painted pottery (Boardman 2001). Scholars have begun to recognize, however, that many of these images may actually depict subjects that have nothing to do with life in Classical Greece and thus that their status as evidence for life in this period needs to be reevaluated (Ferrari 2003).

International Perspectives

The territories that were part of the Greek world in the Classical period cover portions of modern Italy and Turkey as well as Greece, but several other nations in Europe and elsewhere have long histories of engagement with Greek archaeology; these include (but are not limited to) England, Germany, France, and the United States. In addition to establishing archaeological schools and conducting excavations in Greece, these countries hold many objects from the Classical world in their collections. The conditions under which those objects left their countries of origin are not always in line with modern ideas about ethical collecting practices, and calls for the return of objects to the countries in which they were excavated are becoming increasingly frequent. Perhaps the best-known case is that of the Parthenon sculptures (sometimes called the "Elgin Marbles") that reside in the British Museum; in addition to repeatedly requesting their return, Greece has gone so far as to build a new Athenian acropolis museum to hold the sculptures. Less glamorous artifacts have also been the focus of discussions about repatriation, however, and recent years have seen the return of pottery and other objects from museums such as the Metropolitan Museum of Art in New York and the J. Paul Getty Museum in Malibu, California. At the heart of all of these discussions is the question of who "owns" the Classical past and how it can best be displayed and preserved, and at this time there is no scholarly consensus on either question (Neils 2001; Cuno 2008).

Future Directions

This article has already noted a few of the questions and challenges that face archaeologists of Classical Greece, but there are a number of others. One question that has occupied scholars for some time is how to understand the experiences of those members of society whose presence in the archaeological record is fleeting. For instance, fifth- and fourth-century Greek women are known to have

spent much of their time spinning, weaving, and engaging in other tasks relating to the production of textiles, but much of the physical evidence related to these activities is extraordinarily difficult to detect and interpret. With rare exceptions, the textiles themselves have perished, and items such as the loom weights that were found in the houses at Olynthos can tell us only so much about who engaged in weaving, and where, and when. Although Classical texts sometimes refer to women's quarters in Greek houses (Lysias 1), such spaces have been difficult to detect in the archaeological record, and comparative evidence from sites such as Pompeii and Herculaneum suggests that such issues would be highly complex even if Greek domestic sites had been better preserved. Slaves are another group that is often difficult to detect in the archaeological record, although scholars are becoming increasingly aware of the need to attempt to do so (DuBois 2003).

A second challenge that archaeologists of the Classical period face is that of dealing with objects that do not have well-understood excavation histories, of which there are unfortunately far too many. The problem is especially acute for the study of Athenian pottery, much of which was exported to Etruria in antiquity, eventually to be buried in tombs at Vulci and other Etruscan sites (Boardman 2001). Although some of these objects were recovered in controlled excavations, many were excavated illegally before finding their way to the eighteenth-century European art market. Scholars who have attempted to understand both the pottery itself and the Etruscan tombs in which it was once buried are at a large disadvantage as a result of this lack of provenance, so one of the major challenges facing those who study such material is that of reconstructing, to the extent possible, the contexts in which the pottery would have been used and deposited in antiquity.

A third important task archaeologists have begun to undertake is that of reconstructing the ways in which people interacted with built spaces in Classical Greece. Sanctuaries such as those at Delphi and Olympia (Scott 2010), the sanctuary of the Great Gods at Samothrace (Samothrace 2012), and the acropolis at Athens (Ferrari 2002) have all lent themselves to this sort of investigation, and it is to be expected that such studies will become both more common and more refined as technologies for three-dimensional modeling continue to develop.

Clay Pipes in Historical Archaeology

Peter Davey
School of Histories, Languages and Cultures, University of Liverpool, Liverpool, UK

Introduction

In the late sixteenth century, a new class of artifact began to appear within the archaeological record. This was a specially designed receptacle for smoking tobacco which consisted of a bowl in which the tobacco burned and a perforated tube through which the smoke was inhaled. To begin with, in England, clay pipes were made in iron-free, white-firing clays, made in one piece, in two-part molds and fired in specially designed kilns. This technology quickly spread through western Europe and to European overseas colonies, including those in north America from whence, arguably, the idea – though not the technology – had originally come.

By the early seventeenth century, a parallel development occurred within the Ottoman Empire where the earliest pipes – the *chibouk* – were mold-made in red-firing clays but consisted solely of bowls to which were added smoking stems made of wood or reed. They are often described as "stub-stemmed."

Both of these traditions were adopted in different parts of the world, often as the result of trading contacts with European countries. For example, in northern and western Africa, variations of the stub-stemmed tradition were developed. While in Japan, following contact with Dutch merchants, a local form – the *kiseru* – evolved, along with complex patterns of social interaction.

The Archaeological Record

Clay tobacco pipes have been regarded as essential elements in the study of postmedieval excavated assemblages since the 1960s. This is for four main reasons. Firstly, they were mass produced, are brittle and short-lived, have no resale value, and survive well in archaeological deposits. Secondly, they are ubiquitous from the early seventeenth until the late nineteenth centuries. Thirdly, they show chronological and spacial variation making them an ideal type fossil, and finally, they can frequently be identified to maker.

Initially, with their rapidly changing forms and short lives, pipes were valued by archaeologists as a means of dating. In many cases, especially in the period up to 1800, individual forms can be dated to within 20 or 30 years. Although a number of elaborate but still unconvincing statistical dating systems have been evolved, the majority of specialists rely more on formal and decorative detail, together with evidence provided by the marks and stamps of individual makers carried on the pipes.

Wider Interpretative Possibilities

More recently the pipe evidence from excavations has been used for a number of additional avenues of site interpretation. First, given the large numbers often recovered, their chronological range can indicate the degrees of residuality or intrusion for individual contexts. Secondly, as patterns of regional production become more clearly defined, marketing networks on a local, regional, or international scale can be defined. Thirdly, as the contemporary value of pipes was determined by the amount of skill and labor involved in their production, it is possible to compare the socioeconomic status of individual sites by assessing the quality and complexity of the molds used in conjunction with the amount of care and time involved in finishing the pipes once they had been formed. Finally, pipe studies have increasingly focused on the decorative messages carried on them. Possession of a particular style of pipe represented a statement of individual identity. They carry a wide range of symbols of contemporary popular culture, from political slogans to popular song.

Research Issues

While the detail of regional and chronological development is well understood in countries such as the British Isles, the Netherlands, and the USA, for much of the world, the state of knowledge is very patchy (Davey 2009). Regional studies such as the detailed account of Bavaria (Mehler 2010) are essential for the establishment of patterns of trade and influence. The information that they provide can then be brought to bear on the study of patterns of trade at specific sites such as Stade in Germany (Leenen 2013), Eger Castle in Hungary (Varga 2014), or Stari Bar in Montenegro (Gelichi and Sabbionesi 2015).

In the past decade, the availability of digital resources for pipe research has increased almost exponentially. For example, the major archive of published and unpublished material and the world-class collection of smoking-related artifacts held by the Amsterdam Pipe Museum is now accessible online (www.pipemuseum.nl/). Similarly, access to detailed information on the holdings of the National Pipe Archive in Liverpool which is particularly important as a resource for field archaeologists has recently been placed on the internet (www.pipearchive.co.uk). These and similar resources are providing a stimulus for interdisciplinary and multicultural study of the history and effects of tobacco consumption throughout the world.

Clay Tobacco Pipes

Charles C. Kolb
Division of Preservation and Access, National Endowment for the Humanities, Washington, DC, USA

Introduction

Smoking is the practice of tasting or inhaling smoke which is absorbed into the bloodstream, or smoke was blown into or onto individual's healing, ceremonial, or sacrificial rituals. The smoke was produced by burning a substance such as sacred herbs or grasses. The English word "tobacco" originates from the Spanish and Portuguese word *tabaco* which is derived, at least in part, from Taino, a language of the Caribbean Arawak people. Tobacco is a product prepared from the dried or cured leaves of the tobacco plant which is part of the genus *Nicotiana* and of the Solanaceae (nightshade) family. The more potent variant *N. rustica* is native to parts of the tropical New World; today more than 70 species of tobacco are known. Reliable archaeological evidence is scant, but it is believed that tobacco growing began in the New World in the Caribbean and adjacent southern Mesoamerica (what is today southern Mexico and parts of Central America) ca. 6000 BC and by 4000 BC was used in shamanistic rituals (Gately 2007). About 1000 BC, people in the Maya region of Mesoamerica chewed and smoked the leaves of the tobacco plant and mixed the leaves with herbs apparently for medicinal purposes. Tobacco was smoked as rolled leaves – a cigar – or as bits of tobacco leaf burned in a container, censers and pipes. Subsequently, tobacco plants were dispersed by human migration into South America; the Eastern United States received imported tobacco and cultivated native plants. In the Old World, Herodotus described the Scythians of eastern Eurasia as inhaling the fumes of burning leaves, perhaps incense, in ca. 500 BC. The use of handheld devices for burning tobacco has a complex antiquity in both the Old and New World. The most widespread prehistoric distribution of the clay and stone pipes is in the Americas (Gately 2007; Goodman 2005).

Historical Background of Tobacco Smoking

Native American cultures have pipe-smoking traditions, particularly using tobacco, which have been part of their cultures long before Europeans arrived during the Age of Exploration. Early tobacco pipes were drilled hollow tubes of stone, wood, bone, or fired clay, often in the form of a large cigar holder, perhaps replicating the shape from that of a tube of cane. This type is found almost exclusively in the Mississippi River Basin and further west and in northern South America where it was employed to blow out the smoke rather than for drawing it into the mouth. In Midwestern North America, ceremonial pipes were carved from catlinite, a distinctive reddish-colored mineral that was soft, easily excavated, and carved, hardening on exposure to air (West 1934).

In Eastern North America, the prehistoric pipe was modified considerably from the original tube by acquiring a stone or fired clay bowl affixed to a straight or bent stem. Other varieties included the monitor pipe with a bowl set on a flat base perforated as a stem, hourglass pipes, and biconical pipes.

Columbus was likely the first European to see tobacco leaves, although he did not smoke them himself, but one of his crew, Rodrigo de Jerez, observed natives on the island of San Salvador smoking tobacco leaves. He became the first European to partake in the act of smoking and

Charles C. Kolb has retired.

took some tobacco back to Spain where it became popular by 1500. European colonists in the Caribbean had established large tobacco plantations and exported tobacco to Europe by 1530. Apparently Sir Francis Drake brought a consignment of tobacco to England in 1573. In 1586 Sir Walter Raleigh was introduced to smoking tobacco in a clay pipe by the Governor of Virginia, Ralph Lane. Raleigh introduced tobacco smoking at the court of Queen Elizabeth I, and colonists returning from the Americas further introduced it to Tudor English society. This entry focuses on tobacco smoking and varieties of clay pipes produced since the sixteenth century.

Definition of Tobacco Pipes

Tobacco pipes, also simply pipes, are devices for smoking tobacco. The anatomy of a pipe comprises a cup-like chamber, the bowl, for tobacco which is handheld while packing, holding, and smoking the pipe, and a thin hollow stem ending with or without a mouthpiece or bit. The inner chamber of the bowl has a draft hole leading to the hollow stem. Stems were fabricated as a part of the bowl or separately. Bowls of tobacco pipes have been made from briarwood or other dense-grained woods such as cherry, olive, maple, mesquite, oak, and bogwood. Corncob, meerschaum, catlinite, and soapstone were also used. Stems and bits of these types of tobacco pipes were usually made of reed, bamboo, or hollowed-out pieces of wood; more recent stems and bits are made of moldable materials such as vulcanite, Lucite, Bakelite, and soft plastic. Fired clay smoking pipes in the New World were handmade and often decorated by incision, punctuation, or applique, while Old World clay pipes were fabricated in molds which had simple decoration within the mold which would transfer to the bowl and sometimes the stem. Some stems also had markers' marks and occasionally a date of manufacture. One-piece molded clay pipes also had flat heels later replaced by spurs (Fig. 1; Ayto 2002).

The fundamental function of the pipe is to provide a relatively safe, manipulable volume in which to incompletely combust tobacco (and/or other smokable substances) while allowing the smoke drawn from this combustion to cool sufficiently for inhalation by the smoker. Typically this is accomplished by connecting a refractory bowl to a stem which extends and cools the smoke mixture drawn through the combusting organic mass and delivers the smoke from the bowl to the user's mouth. The stem needs a long channel of constant position and diameter running through it for a proper draw.

Manufacturing Clay Smoking Pipes

Clay Selection

There are four main groups of clays: kaolinite, montmorillonite-smectite, illite, and chlorite. Different types of clay, mineral additives, and firing conditions will produce earthenware, stoneware, and porcelain (This section is based on Kolb 1997). In North America, many clay pipes were historically made from more terracotta-colored clays which were also used to fashion pottery vessels. Pipes of terracotta clays were initially introduced into the Old World, but the preferred material was pipe clay or "tobacco pipe clay" which has exceptional bonding properties and plasticity and fires to a white color. European and Colonial American pipe manufacturers selected ball clays, which are kaolinitic sedimentary clays composed of 20–80% kaolinite, 10–25% mica, and 6–65% quartz. A single deposit had variations in composition, including the quantity of major minerals, accessory minerals, and carbonaceous matter. Many authors use the term "kaolin" generically to describe clays that fire white. Finished pipes were not very strong and frequently broke, but replacements were inexpensive.

Fabrication

A bench vice or gin press and simple hand tools were used in the forming process, including knives with specially shaped blades for trimming mold flashing, handstoppers for forming the hole, various smoothing tools, and thin piercing rods of brass or steel (called "wires") for creating the bore

Clay Tobacco Pipes, Fig. 1 Configuration and components of a typical clay smoking pipe (Author's drawing)

in the stem. The gin press was a simple vice with an overhead lever (a "gin handle") which activated a perpendicular rod which terminated with a plunger or "stopper" which was used to punch out and form the bowl interior while the pipe was still inside the two-piece mold; some lever rods had screw mechanisms. A gin press was mounted on a simple bench, similar to a cobbler's bench, and was straddled by the pipe maker. An analogy is the basic mechanism of a hand-operated "juicer" for extracting fruit juice from halved citrus (although the concave and convex surfaces are reversed). The gin handle is used to lower the plunger into the mold to fabricate the bowl interior by pressing the clay into the mold halves, thereby impressing the molded decoration into the bowl exterior and simultaneously creating the bowl interior. However, this procedure was applicable only to forming upright bowls, e.g., those that were perpendicular to the stem, rather than bowls that were attached an acute angle to the stem (Fig. 2). Gang pipe molds made of cast iron are reported for the nineteenth century from Eastern North America.

The piercing rod and mold halves were lightly greased, usually with lard or a light oil, to facilitate the creation of the borehole and removal of the formed pipe. The molder would take the roll of clay, lay it on a work bench, pierce it lengthwise with a rod, and then place the roll into one of the mold halves. The other mold piece was positioned, and clamped with a quick threaded handle, the entire assembly was pressed in either the bench vice or gin press, the latter fashioning the

Clay Tobacco Pipes, Fig. 2 Dutch single pipe brass mold (Author's collection)

bowl interior. The assembly was then removed from the vice, and the rod was rotated so that the stem bore "married" the bowl interior. The hand manipulation of the piercing rod (rotation and back-and-forth movements) and the configuration of the rod itself are significant elements in critiquing the "pipe stem dating" techniques (discussed subsequently in this entry). The pipe maker's initials or name, the name of the towns or production location, cartouches, or rebus might be incorporated into the mold or, less frequently, be separately stamped into the plastic clay bowl or stem. Rectangular stamps with the maker's names were generally confined to one side of the stem. Cartouche marks were stamped on the sides or rear of the bowls beginning in the late seventeenth century and included the initials or name of the maker and the name of the town; dates were also

included. English pipe makers began to discontinue the use of cartouches beginning about 1860.

The treatment of mold lines is a potential indicator of mass production and the relative cost of a pipe. The two halves of the mold employed to form the exterior of the pipe rarely match perfectly, so that a ridge of clay remains along the centerline of the pipe as the mold halves are squeezed in the vice and excess clay is extruded. During the early years of pipe making by hand, this ridge was scraped or trimmed but, in the mass production of less expensive varieties of pipes – where the quantity of pipes produced replaces the quality of the finished product – demonstrates that there was little or no attempt to scrape the mold centerline flat or otherwise to finish the bowl completely. This saving in hand-finishing time is also one possible reason for the development of fluted pipes. In addition to a better finger-grip on the bowl by the smoker when filling the bowl with tobacco (thereby reducing stem breakage), the flutes create an additional technique for centerline mold finishing whereby it was quicker to flatten the mold-line seam along a flute or a vertical noded area than to spend valuable time smoothing the bowl joint on an unfluted pipe.

The stem rod remained in place during the trimming phase of production was removed prior to baking. Excess clay would be trimmed from the bowl top and mold joins with a specialized knife (the "cutter off"), the piercing rod was removed, and the assembly was left to air-dry on a rack or second bench called a "bunch board," each of which held a dozen pipes. Once the clay was leather hard, the mold was removed, and the pipe was allowed to dry further. A thin wire was often passed through the bore to prevent distortion during the shrinking process and facilitate the bending of stems for curved-stem pipes. Skilled artisans were able to fabricate twisted stems; some pipe stems were looped into knots not unlike a pretzel, or stems with spring-like coils were also fashioned. Trimmers and finishers used specialized knives ("trimmers") and burnishing tools to remove rough edges on the more expensive pipes, and the pipe would be inspected for flaws prior to saggar firing. Burnishing tools were made from copper, bronze, iron, horn, or wood. Decorative bowls were retouched with a bodkin. If a simple clamp or bench vice rather than a gin press was used, the bowl top would have to be trimmed with a knife. This was normally done following the long axis of the pipe. The superfluous clay was recycled. Men molded the pipe and fashioned the borehole. Generally, women and girls performed the trimming operations.

"Firing"

Technically, the appropriate term is "baking" rather than "firing" products made from clay. By 1771, three types of kilns for firing clay tobacco pipes were in use and recorded by Oswald (1975) who lamented that few studies of pipe kilns and kiln furniture had thus far been conducted; this condition has since been addressed by Walker (1977) and Peacey (1996) who detail this process. The three kiln types noted by Oswald were (1) small, circular (ca. 4 1/2 ft in diameter) kilns in which pipes were fired in a muffle (a large saggar) or crucible (most authors refer to these as "muffle kilns"), (2) large square kilns (ca. 12 1/2 ft per side) in which saggars were used, and (3) large circular kilns (16–17 ft in diameter), developed by the Dutch, which also used saggars.

Several thousand pipes were baked at one firing in updraft kilns fired with charcoal or wood, and, in more recent times, coal or coke; oak was used as a fuel in the United States (Walker 1977). Small saggars or muffles (large saggars) have been used since the mid-eighteenth century and extensively employed since the early nineteenth century. Pipes were loaded in a vertical position with bowls lowermost in the saggar, or the pipes were stacked directly on kiln shelves. Saggars were of two types, enclosed and open-bottomed; small muffle kilns accommodated at least a dozen saggars.

Bannerman's Eagle Tobacco Pipe Manufactory located at Rouses Point, New York, near Lake Champlain used circular kilns from 1875 to 1884 which could accommodate 500 "baking pots," each holding 280 pipes (Sudbury 1980). One hundred gross of pipes (140,000 pipes) were fired at one time, and a new firing took place every 8 days. A firing schedule at the

McDougall clay pipe factory in Glasgow is reported for 1967 (Walker and Walker 1969). McDougall's had four kilns each capable of taking approximately 300 saggars stacked 10 or 11 high.

Kiln temperatures were raised in increments to ca. 900–950 °C, a "white heat," for between 15 and 20 h, and the subsequent cooling period required up to 3 days. The pipes had changed from "... a dull blue color and very limp and soft, have become perfectly white and hard" (Zorn 1892:37). Walker (1977) estimated an 8–10 h firing at 960 °C. Wasters were rarely salvaged for reuse, often ending as walkway or road fill or rubbish heaps, or thrown in rivers such as the Thames.

Final Finishing

For better-quality pipes, the final stage of manufacture was to dip an inch or more of the mouthpiece or bit into a mixture of soap, gum, and wax, or resin, or sealing wax so that the clay bit would not adhere to the smoker's lips. Noël Hume (1970: 302) believes that the wax coating was introduced only during the eighteenth century. Lesser-quality pipes had their mouthpieces dipped into the same white clay in solution (self-slipping) for the same purpose. Slipping the pipes after a bisque or biscuit firing was practiced in France and, therefore, required a second baking. The more elaborate and expensive pipes were polished with flint nodules; flint blades were used to remove any flashing from the stem hole-bowl junction. Finished pipes were packed in nailed wooden boxes or hooped barrels using wood shavings, sawdust, chaff, or straw for cushioning. The expensive pipes produced by hand were wrapped in tissue paper, in the same manner as high-quality produce is treated today. In England during the seventeenth and eighteenth centuries, a gross was 180, but the standard wooden box during the nineteenth century held 144 pipes. At the McDougall factory in Glasgow, Walker and Walker (1969: 145) report that "... a pipe-maker's gross was the standard 144, but in early parts of the process 192 – sixteen dozen – was a pipe-maker's gross to allow for breakage and rejects." American producers packed 100 pipes per container, but a review of merchants' records suggests that 30, 60, or 75 items per box were not unusual (Akron Smoking Pipe Company 1895).

Clay Tobacco Pipes from England

After the introduction of tobacco from the American colonies and Caribbean in the 1530s, the manufacture of clay tobacco pipes in England began in 1558 (Barber 1879; Higgins 1999; Cambridge 2012; Fox 2015). The earliest written description of smoking was in 1573 and described a pipe derived from native North American types. Alexander (1967), Noël Hume (1970), Oswald (1975), and Walker (1977) discuss typologies based upon English pipe bowl changed through time. Typologies based upon heels and spurs, stem thickness, stem curvature, and stem decorations are reviewed by Walker (1977). The characteristics of bowl decoration are most frequently used to discern types and establish relative chronologies. By 1580 the pipe bowl was barrel-shaped with a flat heel and 1/4″ (6 mm) inside diameter. The bowl and rim were inclined at an obtuse angle to the stem. Stems were 4–6″ (100–150 mm) in length with a borehole of approximately 8/64″ (3 mm) bore down their length. Tudor molds were made initially of carved wood; metals such as lead, brass, bronze, and iron were subsequently used. By 1640 the bowl inside diameter had increased to about 3/8″ (9.5 mm) as tobacco prices continued to fall, although stem lengths remained basically the same. After this date the bowl grew larger, and the stem increased to 10–14″ (250–350 mm). A pointed spur replaced the flat heel, and this design became the standard for the next 60 years. Milled or plain round the rim and occasionally a maker's mark appeared, although generally seventeenth-century pipes were plain. Bowl styles varied from region to region, and by 1680, nearly every town in England had a pipe maker, and clay pipes were the smoking pipe of choice. Production peaked about 1700 and declined thereafter due to snuff taking which became more fashionable but would peak again in the 1850s. The Worshipful Company of Tobacco Pipe Makers & Tobacco Blenders was founded in London in 1619 as a

trade association tasked with regulating the manufacture of clay pipes. Oswald (1975) remarks that there were at least 7200 pipe makers in Britain. Makers' marks appear in a variety of locations on the bowl including on the back, front, and sides, on the base, and on the sides of the spur or heel, as well as on the pipe stems for London ca. 1580–1710 (Pearce and Grey 2009). Oswald (1975) notes that most pipes were unmarked, including 99 percent of pipes manufactured in the early seventeenth century, diminishing to about 40% in the nineteenth century. Higgins has, to date, cataloged 32,000 different pipe stamps (Higgins and White 2017). A primary resource on typologies and chronologies is Davey (1979–2004).

By 1700 the bowl had become more elongated with an inside diameter of about 1/2″ (13 mm), and the stem had a bore of from 3/32 to 1/8″ (2.4–3.0 mm). The size of the bowl gradually doubled in size to hold more tobacco which had become very affordable. Early-eighteenth-century pipes often had flat-bottomed (pedestal) spurs or no spurs at all. By the mid-eighteenth century, very long pipes – called alderman or straws – were introduced which were 18–24″ (450–600 mm) long and with a bore diameter averaging 3/32″ (2.4 mm). These were made for leisure smoking. Some London pipe makers produced rare decorated bowls incorporating heraldic art at this time, and leaf or barley patterns were commonly used to cover seams on the bowl. By 1750 pipes with masonic arms, public house symbols, and military regimental badges were all being made. After 1850 the "yard of clay" or churchwarden pipes up to 36″ (900 mm) in length appeared. Working men, however, preferred a short-stem pipe (called cuttys or "nose warmers") that could be gripped between the teeth while they carried on working. Decorated pipes greatly increased in number and were often used for advertising or commemorative purposes. They were called "fancy pipes" or "fancies," and bore size was reduced to a low of 4/64″ (1.6 mm). In the nineteenth century, three- or four-part molds were used for more complicated designs such as portrait pipes. This was the peak of clay pipe variety and design, when use was at its highest (Higgins 1999). However, clay pipes came under increasing pressure during the late nineteenth century from cigars, briar pipes, and cigarettes.

The National Pipe Archive (NPA) was founded to collect and preserve documentary and archaeological evidence relating to the history and culture of pipe smoking. A publicly available display highlighting the NPA's holdings and research can be seen in the Victoria Gallery and Museum at the University of Liverpool, http://www.pipearchive.co.uk/. The archive has three principal aims:

1. To collect, conserve, and maintain a national archive of the tobacco pipe industry and related matters for the benefit of the public
2. To promote and encourage the general education of the public in the study of the tobacco pipe industry and related matters
3. To encourage archaeological, historical, sociological, and economic research into the subject, by making its collections as widely accessible as possible

The archive's co-curators are archaeologists, Drs. David Higgins and Susie White (Higgins and White (2017); they are also the current editors of the *Society for Clay Pipe Research Newsletter*. This important global resource (1984–2016, 89 vols., 1480 articles) (http://scpr.co/) is being reformatted for the Internet.

The annual English output during the eighteenth century was 750,000 gross – e.g., 108 million pipes per year (Chalkley 1955). The French firm Fiolet at Pas-de-Calais is reported to have 1200 different designs available by the late 1800s, while Gambier, another French firm, offered 2039 shapes. Fiolet had 850 workers who fabricated 200,000 gross of pipes in 1 year, a production of 28.8 million pipes per annum. Clay pipe production became a significant industry in medieval England until the early twentieth century. Major production centers were in and around significant clay and coal fuel sources: London, Manchester, Bristol, Cambridgeshire, Staffordshire, Broseley in Shropshire, Surrey, Southampton, and Stockton-on-Tees, as well as Wales; Glasgow, Scotland; and Dublin, Shannon, and Knockcroghery (County Roscommon), Ireland, where they were called dúidíns. Pipes were also

made in Australia and Canada, France (including painted porcelain forms), the Netherlands (especially at Gouda), Belgium, Germany (Westerwald, Brandenburg, and Prussia), and Austria. Smaller production centers were located in Scandinavia (Denmark, Sweden, and Norway); Iberia (Spain and Portugal); Chioggia near Venice, Italy; the Balkans; and the Turkish Ottoman Empire.

Clay Tobacco Pipes from the Americas

In the Eastern United States ca. 1740, individual pipe makers produced a widely distributed pipe made from a distinctive high-quality, deep red, local clay with large bowl with a short stem into which a longer reed stem was inserted. Pamplin, Virginia, was one of the manufacturing sites, and from 1878 to 1951, the Pamplin Smoking Pipe and Manufacturing Company produced clay smoking pipes which have been studied and a bowl typology of 39 forms published (Hamilton and Hamilton 1972).

Some Bristol makers migrated to New Brunswick Canada, and Scottish pipe makers came to Montreal and Toronto (Walker 1977). The great majority of clay tobacco pipes found in New World contexts were imported from England, with fewer examples from Continental manufacturers.

Dating Pipes: Pipe Stem Dating and Bore Measurements

The technique of seriation, developed by archaeologist James A. Ford for ceramics, is based upon the proposition that artifacts exhibit certain patterns of popularity in a temporal framework. Four dating techniques are available to archaeologists studying seventeenth- and eighteenth-century English clay tobacco pipe stems: Harrington's (1954) histogram of time periods, Binford's (1962) linear formula, Hanson's formulas (1971), and the Heighton and Deagan formula (1972). Harrington's histogram of five basic time periods proved useful to archaeologists, and they critiqued and expanded on the idea. Binford converted the progression to an easily understood mathematical straight-line regression formula (Table 1) that became popular and currently still in use when applied to most pre-1800 British colonial and federal sites. However, Noël Hume and Walker provided examples of Binford's formula that yielded dates that were inconsistent with other dating methods. By 1971, Hanson proposed ten straight-line regression formulas to replace Binford's single formula, but these were still based on Harrington's original study. Heighton and Deagan proposed a curvilinear regression formula in 1972 based on their own bore size research. Despite the passing of four decades, there has been insufficient data generated to adequately test the latter two formulae, likely because they seem "complicated" in contrast to the "simplistic" Binford formula. McMillan (2010) suggests that all the three need to be used in conjunction.

Kolb (1983, 1997) faulted the method itself using data from Barcelona Harbor, Chautauqua County, New York. Among the historic materials excavated from a 1 square meter context in the harbor was an assemblage of 280 fragments of white clay smoking pipes (78 fluted bowls and 202 stems and bits) (Fig. 3.). Apparently packed in a wooden box or crate, this assemblage represents one of the largest unique and homogeneous collections fabricated during a brief period in a single manufactory from only a few molds. Assuming British provenance, stem bore diameters suggest that the specimens dated 1710–1750 CE, while bowl shape and angle of attachment predicated 1780–1820, but descriptive data postulated the period from 1800 to 1860. Borehole diameters are affected by the wire or rod that maker employs to create the bore, so that the occurrence of stems with two different bore

Clay Tobacco Pipes, Table 1 Binford's linear regression

1590–1620: 9/64″ (0.141″) = 3.6 mm
1620–1650: 8/64″ (0.125″) = 3.2 mm
1650–1680: 7/64″ (0.109″) = 2.8 mm
1680–1720: 6/64″ (0.094″) = 2.4 mm
1720–1750: 5/64″ (0.078″) = 2.0 mm
1750–1800: 4/64″ (0.062″) = 1.6 mm

Clay Tobacco Pipes, Fig. 3 Pipe bowl from Barcelona Harbor, New York, USA (Author's drawing)

diameters is not unusual. This can be attributed to the "wiggling" of the wire during insertion and the effect of the displaced clay as it is pushed down the bore. An assessment of a non-English origin is enhanced by the apparent use of a trimming knife on the bowl, suggesting that a simple clamp or bench vice was used to secure the mold halves, rather than the rim having been finished in a gin press. English molds were formed with a slot at the top, into which a knife could be inserted to trim the bowl. This results in trimming lines following the long axis of the pipe. In the Barcelona specimens, the trimming lines run across the top of the pipe and suggest the use of an open-topped mold used in Continental Europe and North America rather than in England. This distinction may be due to the molds themselves or the manner in which the knife was employed. The handedness of the cutter and the orientation of the mold – the bowl versus the stem facing the cutter – may also play a role in this variation.

Future Directions

In spite of research accomplished to date, more specimens from datable contexts and the excavation of pipe kilns are needed. Additional studies of makers' marks, pipe distributions, and related issues are also necessary as is the expansion of research in Continental Europe. A new generation of young scholars should be recruited to follow Peter Davey, David Higgins, Susie White, "Smoke" Pfeiffer, and Byron Sudbury.

Cleere, Henry

Willem J. H. Willems
ICOMOS International Scientific Committee on Archaeological Heritage Management (ICAHM), Faculty of Archaeology, Leiden University, Leiden, Netherlands

Basic Biographical Information

Professor Henry Cleere was born in December 1926 in Croydon, UK. After military service in Italy, Egypt, and Palestine, he pursued a career in the iron and steel industry before becoming involved with archaeology in 1974, as director of the Council for British Archaeology. By then, he had also obtained his Ph.D. for a thesis on the iron industry of Roman Britain. The 1970s was

the heyday of rescue archaeology in Europe, and he became involved in addressing some of the consequences for the profession. One development in the UK was the formation – formally started in 1979 – of what is currently the Institute for Archaeologists (IfA), a professional organization with a code of conduct. Cleere was one of those involved and who developed an interest in archaeological heritage management, from its principles and legal foundations to its organizational and practical applications.

Major Accomplishments

In 1979, he was awarded a Churchill Fellowship that enabled him to study the systems in a number of European countries and build a network in Europe. That led to a book he edited in 1984 called *Approaches to the Archaeological Heritage* (Cambridge), which became very influential. It presented for the first time the management of archaeological resources in a comparative international context. The book was instrumental in discussions in the heritage sector in Europe in the 1980s that in turn led to a decision by the Council of Europe to revise the existing rather obscure treaty on archaeological heritage into what became the Convention of Malta in 1992. By then, Cleere had already published a second important book, extending to many more countries, *Archaeological Heritage Management in the Modern World* (London 1989).

Between 1981 and 1990, Henry Cleere was a member of the Board of ICOMOS, the International Council on Monuments and Sites, and in 1984 established that organization's International Committee on Archaeological Heritage Management (ICAHM). He was a prime mover in the drafting of the 1990 ICOMOS Charter on Archaeological Heritage Management. This was the first time the aims and responsibilities of archaeological heritage management, which were later also echoed in the Malta Convention, were defined internationally.

After his retirement from the CBA in 1991, Cleere started a third career as World Heritage coordinator for ICOMOS in Paris. ICOMOS is the advisor on cultural heritage to the UNESCO World Heritage Committee, and for 10 years, he carried out evaluation and monitoring missions to many sites now on the World Heritage List. Given his experience in international organization and legislation, he was also asked to become involved in the founding committee of the European Association of Archaeologists (EAA) and in 1994 became its first secretary. He also led the working party that brought into being the "EAA Code of Practice" in 1997 and was editor of the newsletter *The European Archaeologist* until 2002.

In 1998 Henry Cleere became honorary professor at the Institute of Archaeology at UCL, and in 2002 he received the fourth European Heritage Prize in recognition of his work.

Clegg, John K.

Jo McDonald[1] and Kate Sullivan[2]
[1]Centre for Rock Art Research + Management, University of Western Australia, Crawley, WA, Australia
[2]Kate Sullivan and Associates Pty Ltd, Balmain, NSW, Australia

Basic Biographical Information

John Clegg was born on January 11, 1935, in Nottingham, UK. He died in Sydney on March 11, 2015, following a long illness.

John Clegg grew up in Cambridge, England, where his mother was an academic. During World War II (aged 5–8), John and his sister were evacuated to stay with an aunt in Vancouver, Canada. During these early years, his lifelong interest in sculpture began. Upon his return John attended The Leys School in Cambridge. He graduated from Magdalene College, Cambridge, with a BA Honours and Certificate in Education in 1959. He received a MA Honours in 1962 from the same University. He had read Geography for 2 years before changing to Archaeology through which he went on several excavations and was influenced by both Eric Higgs and Charles McBurney. After working as a school teacher between 1963 and 1964, he worked as a contract archaeologist, excavating Coygan Cave in South Wales. In 1964 he moved to the University of Queensland in Brisbane to take up an Archaeology tutoring post in the Psychology Department. He soon moved to Sydney University, where he held various positions at the Department of Anthropology and Prehistory, later called Classics and Archaeology. At this time he also studied sculpture at what was later to become the National Art School. Over a 25-year period at Sydney University, he taught hundreds of students how to see, look at, and analyze rock art.

Major Accomplishments

John's Master's Thesis (*Mathesis Words, Mathesis Pictures* 1978) analyzed the Bare Hill rock art body located west of Cairns. This research earned him the University Medal and was among the first in Australia to explore rock art motifs as archaeological artefacts. He was the supervisor to Lesley Maynard (nee McMah) – whose Honours and Masters theses were similarly formative to the way that Australian scholars perceived and analyzed rock art, especially in the absence of a relevant ethnographic context (McMah 1965; Maynard 1979).

In the 1980s and 1990s, John was instrumental in training and fostering the development of a number of rock art scholars and academics at Sydney University (Natalie Franklin, Tania Konecny, Jo McDonald, Laurajane Smith, Meredith Wilson) most of whom went on to undertake doctoral research in Australia, and many of whom are at the forefront of rock art research and/or heritage management today. His Sturts Meadows work in western NSW provided a fertile training ground for many other researchers (including Ben (Robert) Gunn), who were stimulated by John's enthusiasm and quirky theoretical rigor.

John was responsible for introducing the fabulous rock art of the Sydney region to the public with his very popular *Field Guide* (Stanbury and Clegg 1990) which provided information about Aboriginal rock engraving sites around the Sydney region. Produced at a time when there was no public management strategy for this region's amazing rock art sites, *The Guide* provided much needed interpretation and guidance to visitors and subsequent researchers. He produced approximately 60 monographs, reports, academic papers, and book chapters throughout his career, with a focus on methodology and theory in the teaching of rock art. His collaborations with Thomas Heyd on aesthetics have been formative in the development of this theoretical area of rock art discourse.

Clegg, John K., Fig. 1 John Clegg recording engravings at Little Devils Rock (1970). John pioneered the use of polythene and monopods to record large horizontal engravings in the Sydney region. (Photo Kate Sullivan)

John has also had major successes as a sculptor, having been exhibited regularly in the annual Hunter Valley *Sculpture in the Vineyards* and in the Blake Prize in 2010. His fascination for this medium, begun as a child in Canada, has inspired him to produce sculptures throughout his academic career. His interest in the techniques and technologies of rock art influenced the insights which he

Clegg, John K., Fig. 2 John Clegg recording rock art on large horizontal platforms with his monopod, Callan Park (2005). (Photo Kate Sullivan)

Clegg, John K., Fig. 3 John Clegg seated with one of his sculptures at Cedar Creek winery, Wollombi NSW, during Sculpture in the Vineyards Exhibition 2006. (Photo Kate Sullivan)

brought to his analysis of rock art. He undertook experimental work on sandstone in the Sydney region to determine likely time frames required to produce the large engravings on the open horizontal platforms. He conducted similar experiments with Dr. Dan Witter, exploring the making of Panaramitee style engravings in Western NSW (Figs. 1, 2, and 3).

At his memorial service held at the University of Sydney, there was an exhibition of his artworks, curated by his wife of 40 years Dr. Kate Sullivan and his sons Dr. Jack Clegg and Harry Clegg Esq.

Clermont, Norman

David Chicoine
Department of Geography and Anthropology, Louisiana State University, Baton Rouge, LA, USA

Basic Biographical Information

Norman Clermont (Fig. 1) (born 16 October 1940 [Grand-Mère, QC, Canada]) is a Canadian Amerindianist who pioneered the development of field archaeology, ethnohistory, and paleoanthropology in the province of Québec and Northeastern North America more broadly. His publications have explored various topics, methodologies, and culture groups including the history of anthropological thought (Clermont 1978a, b, 1984), field

Clermont, Norman, Fig. 1 Norman Clermont at the André-Napoléon Montpetit site of the Pointe-du-Buisson (1999). (Credit: David Chicoine)

archaeology (Clermont 1982, 1990a), ethnography (Clermont 1977), the Atikamekw (Clermont 1974, 1978c), and the Iroquoians (Clermont 1990b, 1996). Gifted speaker and inspirational intellectual, Clermont occupies a privileged place among the pioneer minds of Québec scientific history.

After studying Classics at the Séminaire Sainte-Marie in Shawinigan and influenced by Marcellin Boule's *Les Hommes fossiles*, Clermont announced during the graduation ceremony his career objective of becoming a paleoanthropologist. He moved to France in 1961 and studied at La Sorbonne under Jean Piveteau (1899–1991), a distinguished French vertebrate paleontologist and member of the French Academy of Sciences at the time. Without an academic scholarship, Clermont worked as a handyman on a cargo ship on his way to France. While in Europe, he participated in archaeological excavations at Paleolithic cave sites in France under the guidance of Eugène Bonifay. In 1962, he obtained a Diplôme d'Études Supérieures en Sciences Naturelles (DES).

Clermont returned to Canada in the summer of 1963 and settled in Montréal where he enrolled in a master's degree program in anthropology at the Université de Montréal. Upon obtaining a MS in 1965 (thesis entitled "Étude comparative de trois mandibules"), Clermont began instructing in undergraduate classes in various departments including anthropology and medicine while working on his PhD dissertation. He completed his dissertation on the "Paléoanthropologie des Anasazis" in 1973. Clermont instructed the first course in Québec prehistory in 1972 and was hired as assistant professor of anthropology in 1973. Under the influence of Gilles Boulet, with whom he had been introduced to the prehistory of his home region of Mauricie in 1959, Clermont pioneered the birth and development of Québec anthropological archaeology and prehistory. He is credited with the creation of the first university program in archaeology in Québec.

While never really abandoning his research in paleoanthropology (Clermont 1979), Clermont taught archaeology and Native American prehistory, as well as developing the first generation of field archaeologists in Québec. Methodologically, he also explored ethnohistory and ethnography (Clermont 1977) and supervised many graduate theses and dissertations on a variety of anthropological topics and approaches. Among the doctoral students supervised by Clermont are Christian Gates St-Pierre, Claude Gélinas, Marie-France Archambault, Évelyne Cossette, Roland Viau, Gérard Gagné, and Claude Chapdelaine (Fig. 2). More than 45 master's theses were also completed under his guidance at the Université de Montréal.

In 1977, Clermont initiated the first field school in Québec at the archaeological complex of Pointe-du-Buisson in Melocheville. The field school, held every August until 2000, would become the main training ground for Québec prehistoric field archaeologists. In the classroom,

Clermont, Norman, Fig. 2 Norman Clermont (right) and Claude Chapdelaine (left) at the Laboratoire d'archéologie du Département d'anthropologie de l'Université de Montréal (circa 1979). (Credit: Pierre Corbeil)

Clermont was famous for his expressive and inspirational lectures, especially the always well-attended introductory course on human evolution and prehistory entitled "Éléments de Préhistoire." He retired from the Université de Montréal in 2002 after 29 years of teaching, research, and service.

Major Accomplishments

Clermont's contributions to archaeology are multiple and durable, as he almost single-handedly built the first academic program of Québec anthropological archaeology, as well as helped train the first generation of field excavators. In addition to his pioneering role as a lecturer, field supervisor, and graduate mentor, he popularized and standardized the production and publication of archaeological research in French. Clermont's service as associate editor for the *Journal Canadien d'Archéologie* demonstrates his commitment to the francophone production of archaeological knowledge. In addition, he served as vice-president of the Canadian Archaeological Association.

As an intellectual, Clermont's publications stand the test of time and exemplify the breadth and depth of his anthropological interests. His contributions explore various topics including paleoanthropology, prehistoric archaeology, ethnohistory, ethnography, and the history of anthropological ideas. Prolific, yet concise, Clermont's prose is famous for its clarity (e.g., Clermont 1999). As such, his 150+ published works are addressed to both specialized and lay audiences. Clermont authored 9 books and edited 8 volumes, in addition to writing 44 articles on prehistory, 21 on ethnohistory, 9 on the history of anthropology, 5 on paleoanthropology, and 26 on various other topics (see Chapdelaine and Corbeil 2004).

In the field (Fig. 3), Clermont was famous for his extreme rigor, attention to methodological details, as well as indefatigable enthusiasm, good humor, and intellectual generosity. Leading by example, he systematically and diligently organized his thoughts, research questions, and reading notes into index cards, a technique that inspired many of his students.

Clermont's pioneering role in Canadian archaeology has been recognized and honored through a series of well-deserved awards including the Prix de reconnaissance from the Association des archéologues professionnels du Québec (1994), the Prix ICOMOS Canada for his exceptional contribution to the cultural heritage of Québec (1996), the Prix Gérard-Morisset (Québec) (2002), and the Prix Smith-Wintemberg (Canada) (2002). As eloquently pointed out by his colleague Charles Martijn (1934–2016) in 2002 when Clermont received the Prix Smith-Wintemberg, Norman was the "Principal architect

Clermont, Norman, Fig. 3 Norman Clermont at the station 3 site of the Pointe-du-Buisson (1999). (Credit: David Chicoine)

of the professionalization process which Québec prehistory research underwent in the second half of the 20th century."

Closet Chickens

Joe Watkins[1,2] and Deborah L. Nichols[3]
[1]Archaeological and Cultural Education Consultants, Tucson, AZ, USA
[2]Archaeological and Cultural Education Consultants, Takoma Park, MD, USA
[3]Department of Anthropology, Dartmouth College, Hanover, NH, USA

Introduction

The history of the "Closet Chickens" has been recounted by Atalay (2006: 269–271) and Echo-Hawk (2010a: 95–96) and will only be briefly described here primarily as a means of creating a shared context for the group. There is no single origin of the group, but there are shared remembrances that seem to correlate with an agreed-upon history.

Definition

The nucleus of the "Closet Chickens" developed out of a conference held at Dartmouth College in May 2001 titled "On the Threshold: Native American-Archaeologist Relations in the Twenty-first Century." The conference, funded by the Wenner-Gren Anthropological Foundation with support from Dartmouth College and led by co-organizers Deborah Nichols and Joe Watkins, brought together a large number of archaeologists of Native American heritage in an attempt to evaluate the relationships between archaeologists and Native American communities. Holding the conference at Dartmouth seemed especially appropriate as the history of the College in broad respects shares with the history of Native American-archaeology relations. Founded in 1769 to educate "youth of Indian tribes," few actually graduated from the College until it reaffirmed its commitment in the 1960s, nearly 200 years later. In addition to the organizers, participants came from universities, museums, and tribal and federal agencies across North America and included Richard Begay (Navajo, Navajo Nation), Robert Begay (Navajo, Navajo Nation), Janine Bowechop, now Ledford (Makah, Makah Cultural and Research Center), Colin Calloway (Dartmouth), Roger Echo-Hawk (Pawnee Nation of Oklahoma, Denver Art Museum), Dorothy Lippert (Choctaw, Smithsonian Institution), Desiree Renee Martinez (Gabrielino, Harvard), Deborah Nichols (Dartmouth), John Norder (Spirit Lake Dakota, Michigan State), Dean Suagee (Cherokee, Vermont Law School), and Dale Turner (Teme-Augama Anishnabai, Dartmouth). We hoped the conference would be a springboard for continuing dialogue, which it has in ways we could not have imagined. Continuing discussion of the issues raised at the conference on emails led to the establishment of a more formal group that began as a nameless Listserv aimed at expanding not only the discussion but also the parties involved in it.

The name "Closet Chickens" arose during email exchanges as the group sought a name for itself. The word "Chicken" was associated with a movie watched in the evening by conference participants in their hotel. "Closet" was subsequently added after an email exchange where one member offered the room in a closet of a small apartment to others attending a professional meeting (Atalay 2006). The Closet Chickens are "birds of a feather" who do tend to flock together. Many of its members are of American Indian or other Indigenous descent who practice archaeology, but there are non-Indian members as well. In general, it is an online support group that discusses various issues as they arise. Often comments relate to contemporary issues that impact the practice of archaeology by Indigenous group, but as often other threads of discussion relating to repatriation, ethics, decolonizing the discipline, Indigenous Archaeology, and many other issues arise. Many of the established archaeologists on the Listserv are mentors to the professionally younger archaeologists who participate.

Future Directions

The list serves as an email discussion forum where topics are often subjected to scrutiny. Occasionally discussions become heated, but more often than not such discussions end when the participants have seemingly discussed the issues to completion. It is a support system that has helped young archaeologists who often feel to be on the outside of a general archaeological trajectory. In addition, the Closet Chickens is important in terms of contemporary American archaeology in that it provides a semi-protected forum for archaeological practitioners whose perspectives tend to mesh with Indigenous ideas concerning the colonialist practices of anthropology and archaeology and who work closely with tribes and First Nations and Indigenous communities. This forum allows members to openly discuss ideas and issues that might be too sensitive for discussion in a truly "public" forum. It also permits younger members to speak candidly about issues they have or are encountering in their readings, study, and early careers and discuss strategies to address them.

Secondly, and somewhat importantly, the Listserv allows for ease of mentoring between those who have been "in the business" for longer periods to help others who are in the early stages of their careers or education tenure. Professional

advice, open reading of materials, sometimes controversial discussion on topics, and even internal disagreements help us to understand not only what our own perspectives and viewpoints are but also to understand how our ideas have grown and continue to grow. It also provides a protected space within which to relax.

The primary focus of the Closet Chickens is on continuing the conversation about the impact of archaeology globally on the heritage of Indigenous populations. Archaeology, once known as the handmaiden of colonialism, is continually challenged by Indigenous people to become accountable to the cultural groups whose heritage is under scrutiny. The Chicken network allows a safe area for discussion outside of the academic processes, where students can gamble with ideas and points and where established professionals also can openly discuss ideas without fear of retribution or ridicule.

The group has expanded each year since its inception, and we hope that over the course of the next decade, a larger group of younger archaeologists who are attentive to Indigenous concepts of culture will be able to contribute to a more rounded practice of anthropology and archaeology. Members "nominate" others who they feel would contribute to the discussions on the Listserv. We have non-Natives, Natives, Australians, Maori, and a generous mix of non-described individuals who contribute to the discussion in numerous ways. The group is not all-inclusive and has had some in-depth discussions about individuals who were precluded from the "flock" after some intense and often heated deliberations. More established archaeologists try to stay outside of discussions as much as possible (perhaps too much on occasion) as we generally believe the Closet Chickens is a place for younger people to test their wings, but we do chime in as necessary, especially to encourage debate and discussion.

Many of the members of the Closet Chickens may be what Roger Echo-Hawk decries as "stakeholding Indians—self-identified adherents to racial Indianhood . . . wielding Ph.D.s and trowels as they circle the archaeological meta-narrative" (Echo-Hawk 2010b: 21). While it is true that many are on the cutting edge of attempting to increase the reach of Indigenous Archaeology as it hopes to "decolonize" the practice of archaeology, it is not a political group (although many of its members do have political perspectives relating to the practice of archaeology as a social science). It is not a racialist group but allows that people with a base in American Indian cultural life create a shared understanding of the impact of archaeology on cultural groups worldwide. The group has grown quiet recently, perhaps signaling an end to its utility. Only time will tell.

Clovis and Folsom, Indigenous Occupation Prior to

Paulette F. Steeves
Department of History and Philosophy, Algoma University, Sault St Marie, ON, Canada
Mount Allison University, Sackville, NB, Canada

Introduction

The first modern human migrations to the Western Hemisphere (the Americas) are now discussed as being much earlier than previously

thought. The historical Clovis First hypothesis of initial human migrations to the Western Hemisphere (the Americas) was postulated on an entry route across the exposed land mass of Beringa no earlier than 11,000–12,000 years before present (ybp), an inland migration route through a narrow treeless ice-free corridor, and dating of Clovis tools found in association with extinct mammals near Clovis, New Mexico, in the 1920s (Adovasio and Page 2002). Archaeologists argued that the first people to enter the Western Hemisphere brought the Clovis tool technology with them when they walked across the Bering Land Bridge from the Eastern Hemisphere area we know today as Asia.

However, the tenets of the Clovis First hypothesis of initial migrations to the Western Hemisphere (the Americas) have been critiqued as unsubstantiated (Cann 2001). Archaeologists are uncertain about the dates for initial modern human migrations and the possible migration routes into the Western Hemisphere. Today many archaeologists agree that the Clovis First hypothesis is not supported by archaeological, genetic, or linguistic evidence (Cann 2001; Nichols 1990). The question now is how much earlier were people present in the Western Hemisphere? There are hundreds of archaeological sites distributed throughout North and South America which suggest a minimum possible date of 40,000 years before present (ybp) for initial migrations (Steeves 2015a, b). The number of sites that date between 40,000 to over 200,000 is much smaller, yet peer reviewed articles by respected archaeologists report on sites within this date range. Therefore, we must remain open-minded to the possibilities of much earlier initial human migrations into areas of the Western Hemisphere, during the Pleistocene.

Definition

Pre-Clovis Sites: Archaeology sites in the Western Hemisphere (the Americas) which date to earlier than the known dates for Clovis or Folsom lithic technologies, or that date earlier than 11,200 ybp.

Key Issues

To say the debate over the timing of initial migrations to the Western Hemisphere has been a contentious issue in American archaeology would be an obvious understatement. A small group of archaeological authorities commonly known as the Clovis Police defended the unproven Clovis First hypothesis of initial migrations for many years. This very vocal group of archaeologists denied a human presence in the Western Hemisphere prior to 12,000 years ago, and their opposition blocked funding and research into earlier initial migrations, for decades. In recent years, it has become clear to archaeologists that there has never been any solid archaeological evidence to support the tenets of Clovis First hypothesis of initial late entry migrations to the Western Hemisphere. However, there have been numerous archaeology sites published on in both North and South America which pre-date 13,000 ybp (Steeves 2015a, b). There are hundreds of reported pre-Clovis sites many of which have met or exceeded rigorous archaeological criteria for site legitimacy, and others which have provided evidence which warrants further investigations and testing of sites. Archaeologists have begun to reevaluate previously reported pre-Clovis sites in both North and South America and to publish multidisciplinary research which discusses the possibilities for and evidence of earlier initial migrations to and habitations of both North and South America.

Archaeological criteria for site legitimacy have been met by many earlier sites including Coats Hinds with a date of 12,869 ybp (Deter-Wolf et al. 2011) a mammoth kill site in Tennessee which was nominated and accepted to the United States National Register of Historic Places (NRHP) in 2011. Monte Verde, an open-air site in Chile excavated by Tom Dillehay and dated to 13,525 ± 250 ybp has produced a vast body of evidence for earlier migrations. Monte Verde also produced a date of 33,370 ± 530 in a lower level (Dillehay 1997).

Recently, new testing and excavations of sites, such as Blue Fish Caves (Alaska) 24,000 ybp (Bourgeon et al. 2017), and Page Ladsen

(Florida) 14,550 ybp (Halligan et al. 2016), have supported earlier archaeological reports of pre-Clovis dates at the sites. All pre-Clovis sites were previously denied by many in the archaeological community. The new research and dating supporting earlier than Clovis archaeology sites reflects a changing view among a select group of North American archaeologists.

Research from other fields such as linguistics and genetics has also produced evidence for earlier initial migrations. The great linguistic diversity of Indigenous peoples of the Western Hemisphere (the Americas) suggests that minimally, 20,000–50,000 years would have been required for such a high number of language families to have developed (Nichols 1990). Molecular research has suggested time frames for initial migrations as early as 40,000 ybp and as late as 22,000 ybp (Mann 2005). There are records of physiological and cultural diversity across the expanse of both North and South America at the end of the last glacial maximum. Therefore, to allow for such diversity to have developed across such distant areas, scientists must consider the time required for geographical distance, environmental adaptations, and cultural developments across time and space prior to the end of the last glacial maximum.

Important to discussions on initial human migrations to the Western Hemisphere (the Americas) is the history of global intercontinental human and mammalian migrations. The Bering Land area was dry and above water many times throughout the Pleistocene, and an inland corridor was open as early as 75,000 years ago (Adovasio and Page 2002). Early humans had adapted to ecological niches in all areas of Africa, Asia, Europe, and Australia and reached islands such as Java and Crete thousands of years prior to 12,000 ybp, which is evidence that suggests early humans had the tools and technology to travel and to adapt to all environments for hundreds of thousands of years prior to the end of the last glacial maximum. Mammals that arose in the Western Hemisphere such as horses, camels, and sabertooth cats all had to walk across a land mass to reach the Eastern Hemisphere. The biotic exchange between the Eastern and Western Hemispheres has taken place for millions of years. Where four-legged mammals walk and migrate so too then can two-legged. *Homo erectus* and archaic *Homo sapiens* sites dating to over 1.8 million years ago have been found in the Eastern Hemisphere. Thus, we know that *H. sapiens* were present in Asia during times when the northern latitudes were being accessed by mammals migrating between the two hemispheres. We must then remain open to the possibilities of earlier human migrations as well.

Current Debates

Current debates on initial migrations to the Western Hemisphere (the Americas) include competing hypothesis of possible migration routes and times. Kurt Fladmark (1979) and Erlandson et al. (2007) have both discussed the possibilities of an ice-free coastal migration route along the Pacific. A North Atlantic ice edge corridor migration route has been discussed by Dennis Stanford and Bruce Bradley (2004) who suggest that Clovis technology may have descended from the Solutrean technology found in areas of present day France. Recent research on lithic technologies has also highlighted the possibilities of earlier than Clovis lithic technologies in the Western Hemisphere (the Americas) (Beck and Jones 2010), and the fact that lithic tools which are not definitively Clovis are often found in the same stratigraphic levels as Clovis technologies.

Another much earlier site reported in a peer reviewed publication is the Cerutti Mastodon site formerly known as the State Route 54 Mastodon Site, located in southwestern California just a few miles north of San Diego. The Cerutti Mastodon Site was recorded and analyzed by

archaeologists and Paleontologists who were very familiar with the geology of the area. The materials they collected are in impeccable order and curated to allow for study without disturbing the samples. Many of the fossils were completely coated in a caliche shell, which was left intact or removed and retained (Holen et al. 2017). Casts of large tusks were made allowing fossil specimens to remain in the soils in which they were deposited. Human presence at the Hwy 54 site was suspected due to the assembledge at the Mastodon Quarry collection area (non-fluvial), which contained a large deposit of spirally fractured bone around mid-size boulders, and the in situ placement of a mastodon tusk. Given the denial of early humans in the Western Hemisphere, the archaeologists and scientists (Holen et al. 2017) took years to complete studies and testing of the site materials before they published on the site. However, the Cerutti Mastodon Site has recently been dated to minimally 130,000 years before present (Figs. 1 and 2). It is very interesting that in this area between southern California and central Mexico there are at least eight other sites that date to over 100,000 years. This is the only area of the Western Hemisphere with a group of sites that have reported possible dates of over 100,000 ybp.

Future Directions

Future directions in the study of initial human migrations to the Western Hemisphere (the Americas) include the reevaluations of hundreds of sites. It is now accepted by most archaeologists that humans entered the Western Hemisphere (the Americas) earlier than 13,000 ybp. Research to locate areas of potential earlier habitation may expand to include testing of new areas of high probability or regional areas of earlier habitation sites (Figs. 3 and 4).

The understanding of possibly earlier than Clovis technologies has been the focus of recent publications such as the work of Charlotte Beck and George Jones (2010) who have argued that Western Stemmed points are earlier than Clovis points in the inter-mountain west. Research on lithic technologies, cave painting, petroglyphs, molecular studies, residue analysis, geological studies, and linguistics are building a multi-dimensional understanding of the possibilities and evidence for initial migrations to the Western Hemisphere. Future directions in archaeological studies of the first people of the Western Hemisphere (the Americas) include gaining new insights from old collections and renewed excavations of previously recorded Pleistocene sites and areas.

Examples

There are hundreds of published reports of Pre-Clovis sites (Figs. 5 and 6) in both North and South America. The following list is a sample of some of the most discussed sites. Some of the sites included in this list are pre-12,000 ybp sites which are recognized as national or global heritage treasures and are listed in the United States National Register of Historic Places (NRHP) and the United Nations Educational Scientific and Cultural Organization (UNESCO). Many pre-12,000 ybp sites in North and South America have been excavated, dated, and published by more than one archaeologist or group of archaeologists at different times.

This list will provide the name and date of a main or recent publication on a site. However, there may be numerous site reports, critiques, and responses for each site mentioned which are not listed in the following chart (Table 1). Where a range of dates or more than one date is listed this usually represents numerous cultural levels within site in a stratigraphic sequence, the following chart does not necessarily list every date, earliest or latest for each site (Fig. 6).

Clovis and Folsom, Indigenous Occupation Prior to, Table 1 Sample only pre-12,000 ybp archaeology sites North and South America

Site name	Dates reported	Site location	Site publication authors
Ceretti Mastodon Site	130,000 ybp	Southwestern California	Holen et al. (2017)
Pedra Furada	50,000 ybp	Brazil	Guidon and Delibrias (1986)
Pendejo Cave	55,000 ybp	New Mexico	MacNeish and Liddy (2003)
Woolly Mammoth	40,000 ybp	California	Berger (1980)
Burnham	32,000 ybp	Oklahoma	Wyckoff (1999)

Clubs and Societies Promoting Archaeology (National and Local)

Suzie Thomas
University of Helsinki, Helsinki, Finland

Introduction

There are opportunities to become involved in archaeology as an unpaid volunteer in numerous projects across the world. For example, high-profile excavations such as Çatalhöyük in Turkey (Çatal News 2010) and Quseir in Egypt (Tully 2007) involve local community participation.

Other projects have involvement from international initiatives such as Earthwatch (www.earthwatch.org) that encourage volunteers to join different "expeditions," including archaeological and paleontological research projects, at a variety of locations across the world.

However, as well as projects led by paid archaeologists and trainers, there is also a wealth of voluntary groups, clubs, and societies, sometimes referred to as "amateur" or "avocational" organizations, many of whom carry out work independent of other projects. This section defines and discusses the range of activities, locations, and people that represent these groups.

Definition and Historical Background

Club, groups, and societies that promote archaeology, at both national and local levels, are primarily membership organizations, where an annual fee is usually required to join. In some rare cases, membership can be via invitation only, for example, if membership to the society in question, for example, the Society of Antiquaries of London (for which members are entitled to list the abbreviation "FSA" – Fellow of the Society of Antiquaries – after their name), is seen as an esteem indicator. However, the vast majority of groups do not have restrictions to their membership in this respect, and some offer concessionary fees, for example, for students, unemployed, or retired. In all cases, the groups consist of voluntary members (in other words unpaid), although a small number have some paid staff funded, for example, paid secretaries funded through membership fees to ensure administration takes place or project officers for specific grant-supported activities. This does not preclude people who work professionally as archaeologists from joining such groups (and indeed many archaeologists are members of local groups – e.g., the author of this entry was, at the time of writing, on the Committee for the Yorkshire Architectural and York Archaeological Society) along with members who may not have training in archaeology but nonetheless are interested in the subject. However, the key element of membership is that it is voluntary, rather than paid.

Groups, clubs, and societies vary in terms of their areas of interest, size of membership, and even level of activity. Hence, the organized groups which voluntarily interact with archaeology in the early twenty-first century are both vibrant and diverse. This is particularly the case in the United Kingdom, which has often been credited with having a particularly strong tradition of amateur and independent archaeology (e.g., Fry 2007: 21). Recent research shows that these groups seem to have grown in number in recent years, with there being more than 2,100 voluntary groups across the UK alone, compared to possibly just over 400 such groups in the 1980s (Thomas 2010: 12). Yet the origins of some of these groups go back to the nineteenth and eighteenth centuries, while others have formed in much more recent times. It is not only the age of groups that varies, as there is also a vast range of interests and also types of activities enjoyed by clubs and societies.

The oldest of groups involved with archaeology and related disciplines are often the Antiquary Societies, which formed as learned antiquarian groups, often with an element of exclusivity maintained, for example, through restricted membership. The two biggest in the UK today are the Society of Antiquaries of London (founded in 1707) and the Society of Antiquaries of Scotland (founded in 1780). Both of these groups have nationwide interests (UK-wide in the case of the former, Scotland-wide for the latter) and take in disciplines beyond archaeology alone. Other antiquarian groups, such as the Society of Antiquaries of Newcastle-upon-Tyne (founded in 1813), have more of a regional focus to their interests. One of the oldest local antiquarian groups still in existence in the UK is the Spalding Gentleman's Society in Lincolnshire, which was founded in 1710. This group, until very recently, was exclusively male only in its membership. Activities vary in these groups, but lectures are a key component, as are publications and schemes for support for current scholarly research. In the case of the Spalding Gentleman's Society, there is also a private museum featuring an eclectic collection of antiquities and curios that are cared for by the society members (all volunteers), reflecting the antiquarian roots of the group.

County archaeological societies can be almost as old as the antiquarian groups, such as Berkshire Archaeological Society which was founded in 1871 or London and Middlesex Archaeological Society, founded in 1855. They can be found across the UK – reflecting in their areas of interest history, archaeology, and even architectural history connected with their chosen geographic area. County archaeological societies often have a standard range of activities that are offered, such as an annual lecture series, excursions, and a newsletter and/or journal. However, it is wrong to assume that these groups are not necessarily more active than this in their archaeological investigations, as several also carry out regular archaeological fieldwork or partner with other archaeological organizations, such as universities or archaeological contractors depending on the project, providing volunteers and other support. This can be seen, for example, with the Architectural and Archaeological Society of Durham and Northumberland, which is a partner alongside Durham University, Stanford University, and Durham County Council for excavations at the Roman site of Binchester in County Durham (see www.durham.gov.uk/pages/Service.aspx?ServiceId=6915).

There are other societies which cover more than just archaeology in their remit of interest that nonetheless get involved in archaeological work, such as field walking, excavation, or recording or graveyards, the last of which is often connected with family history research. Examples include natural history societies, such as the Belfast Natural History and Philosophical Society, that support "research and publications about Ireland and Ulster's cultural and material environment," including archaeology (http://belfastsociety.com/index.html). Similarly, La Societé Guernesiaise on Guernsey, a UK Crown Dependency in the Channel Islands, comprises several "sections," including botany, literature, and archaeology. Due to the lack of an archaeological contractor on the island, with just three archaeologists employed at the island's museum, Archaeology Section members have ample opportunity to participate in any archaeological fieldwork taking place. Therefore, local history societies, natural history societies, and even civic societies can cover archaeological research and activities in their range of interest. This is in part due to the holistic nature of archaeology, taking in as it does standing buildings, graveyards, field walking, archival research, as well as what are sometimes perceived as more "typical" activities such as excavation and geophysical survey. It is also a reflection on the diversity of interests that many voluntary groups have, for example, a civic society concerned with improving their local neighborhood may well take an interest in conserving the more historic aspects of their surroundings.

Some archaeological and heritage societies act as umbrella societies for smaller groups. In some ways this is the case with the Council for British Archaeology (CBA), as it has both individual membership and affiliate membership – with affiliates including both professional organizations such as university departments and archaeological contractors but also voluntary groups. Furthermore, there are regional groups of the CBA – one covering Wales and 11 across England, all of which interact with and have membership from local groups within their regional coverage. There are also umbrella organizations that work on a regional level, such as the Federation of Ulster Local History Societies (Northern Ireland), Community Landscape Archaeology and Survey Project (comprising individual members and 12 local heritage groups in Northamptonshire), and less formal community heritage forums such as the recently established West Yorkshire Community Heritage Forum, through which local groups, practitioners, and other stakeholders share ideas and experiences and meet regularly to update each other on their recent activities.

One category of group that can cause controversy in the archaeological community, even though they frequently interact with archaeological material, is artifact hunting. Often also known as "treasure hunters," these are most often metal-detecting clubs and societies in the UK, a hobby that in previous decades has also been known as "coin spotting" or "coin shooting." Other forms of artifact hunting include pot hunting, as is common, but not always necessarily legal, in the USA (Hicks 2006: 140). There is often perceived to be a "grey area" between legal treasure hunting and illicit activity, such as nighthawking (as illegal metal detecting is known in the UK) or the activities of

looters in countries such as Italy (known as *tombaroli* – Brodie 2006: 5) and Peru (known as *huaqeros* – Watson 1999; Skeates 2000: 56). However, as has been shown by the outreach work of organizations such as the Portable Antiquities Scheme (www.finds.org.uk), metal-detector users can and do make a meaningful contribution to archaeological knowledge when they share their finds information with the archaeological sector and follow good practice advice and guidance. Hence, while there are still some issues of discourse between the metal-detecting community and other groups that engage with archaeological heritage, it is important to maintain dialogue.

Self-identified community archaeology groups form another category of groups and societies promoting archaeology, while there is overlap with other voluntary groups, in the sense that they are generally made up of members of the local community wishing to engage with archaeological heritage in different ways. However, increasingly, groups are forming that deliberately self-identify as "community archaeology groups" (rather than, e.g., archaeological societies or local history/heritage groups). Many of these have formed only in recent years, in the case of the UK often triggered by the availability of funding from major voluntary sector grant streams such as the Heritage Lottery Fund (www.hlf.org.uk), which funds specific projects around different types of heritage activities, designed to engage with local audiences. As a result, many groups formed in order to access a grant for a project but then continued following the end of the grant. "Community archaeology" can also be seen as a term going beyond those already active in local groups, with many projects (not necessarily led by communities themselves but often led by heritage professionals such as museum archaeologists or archaeological contractors) designed specifically to attract new audiences to archaeology that may not become involved otherwise.

Key Issues and Current Debates

There are a number of issues connected currently with groups and societies involved with archaeology. A key issue in various countries is that of access and legality. For example, in most countries some or all sites of archaeological significance are legally protected from any invasive investigation without permission. This of course protects the sites in question (although it does not necessarily stop illegal excavations, illicit metal detecting or other activities), but it also provides a barrier to independent investigation by voluntary groups. For example, while many areas are open to archaeological investigation in England and Wales, provided that there is permission from the landowner and the site is not a Scheduled Monument or other protected area, in Northern Ireland all excavation is strictly prohibited without the procurement of a license from the Northern Ireland Environment Agency. In practice, this is usually only granted to professional archaeological organizations, and as a result in recent years, there has seemingly been only one voluntary group that has managed to carry out its own excavations, which had to take place with the assistance of a professional archaeological contractor. In Europe, some 46 countries are signatories to the European Convention on the Protection of the Archaeological Heritage (revised) 1992, commonly known as the Valletta Convention (Council of Europe 2011). This convention emphasizes the professional side of archaeologists but has also led to concern by some that there is a risk of excluding public participation depending on how the convention is interpreted (e.g., The Archaeology Forum 2006). Hence, this may have an impact on the extent to which "amateur" archaeologists and others are able to engage with archaeological heritage independent of professional supervision.

Another important issue that causes concern not only to paid archaeologists but also to members of local groups and societies is that of training and standards. This has had two effects in particular. On the one hand, there is a perception among some paid archaeologists that work carried out by voluntary groups will be substandard, with poor and out-of-date methods used for archaeological fieldwork.

This has led to some from the voluntary sector accusing professional archaeologists of elitism and exclusivity in their attitudes towards

archaeological heritage (e.g., Selkirk 1997: 9). Research into participation in archaeology in 2003 by the CBA suggested that some of the project's respondents "spoke of professional elitism and a closed shop; there was a feeling that archaeology is 'done by professionals for professionals' and that professionals are no longer willing to admit or impart a sense of excitement" (Farley 2003). This is also reflected in the concerns that members of the local community are rarely involved in commercial archaeological work, certainly in the UK, with few notable exceptions such as the Hungate excavation in York City Centre (Connelly 2011). There are often reasons why volunteers cannot be involved in commercial projects, such as health and safety restrictions, time limitations (it generally takes longer to carry out fieldwork when volunteers are involved due to the extra supervision and training needed), and even client confidentiality clauses. However, the emergence in England of the *Planning Policy Statement 5* in England (see www.communities.gov.uk/publications/planningandbuilding/pps5) suggests opportunities for greater community involvement in all aspects of archaeological heritage management in the planning process, from decision-making to active hands-on participation. This has been noted recently in recommendations to the archaeology sector in the UK (Southport Group 2011: 8, 10–13).

However, there are also genuine issues with regard to the activities of some voluntary groups in the negative effects that their work can have on the archaeological heritage. Perhaps one of the most obvious examples of this comes from the activities of artifact-hunting groups, such as metal-detector users and pot hunters, as their search for specific artifact types can lead to the destruction of the archaeological *context* surrounding that artifact, without the recording of associated artifacts and materials, and causes irreversible damage and loss of knowledge. However, this is also true of intrusive investigations such as field walking or excavation, which are, by definition, destructive. Some groups have acknowledged this, and there is a demand for training opportunities which is not always met due to the impact of the current global economic downturn and changes in priorities. For example, there are now significantly less continuing and adult education courses available through English universities than even a few years ago, courses which traditionally were a key source of training for voluntary groups (Lee 2009: 10). This lack of training is often compounded by the failure of many groups to inform local and national record keepers, such as (in England) the Historic Environment Record Officer in their local authority area of work they have carried out and the results of that work. However, in some areas there are community archaeologists: paid archaeologists who facilitate, train, and support the voluntary sector in archaeology. In some cases, such as in Shropshire, Surrey, and Herefordshire, a community archaeologist has been in the employment of the Local Authority – although these positions have decreased in the past few years in the UK due to local government reductions. In other cases, independent charitable trusts such as York Archaeological Trust employ community archaeologists, demonstrating the need for archaeologists with an outward-facing, inclusive, and informative role within an organization. Recognizing the need for archaeologists with the so-called soft skills necessary to engage with a wide range of different people from diverse backgrounds and with varying abilities, the CBA recently started a three-year training program for future community archaeologists – the Community Archaeology Bursaries Project – with funding from the Heritage Lottery Fund, English Heritage, Cadw, and Historic Scotland (see www.britarch.ac.uk/community/bursaries). These trainees, 39 in total over the project's duration, will learn how to interact with the voluntary sector in archaeology, including gaining experience of organizing, delivering, and evaluating bespoke training sessions.

Another factor that may have an impact on archaeological activity at a global level is the effect of the economic downturn faced by many countries. Certainly in the UK, this has contributed to the loss of many archaeological jobs, with an estimated fall of 7.6% from July 2010 to January 2011 (Aitchison 2011: 2). It is certainly feasible that over the next few years, there will be an increase in the activity of local groups and societies, as the activity of paid

archaeologists recedes. Furthermore, many of these groups work for a long period on the same site or related sites, often in areas where commercial archaeology would be unlikely to operate, for example, in an area where no development is planned. The increased activity of voluntary groups and societies will depend too on the extent to which the countries in which groups are based have legal constraints affecting the access to archaeological sites and projects by volunteers.

Côa Valley Rock Art Sites

António Martinho Baptista
Parque Arqueológico do Vale do Côa, Vila Nova de Foz Côa, Portugal

Introduction

The first engravings (Chalcolithic/Iron Age) were found in 1982 at Vale da Casa, a Douro terrace near the Côa River's mouth (Baptista 1983), the first site of the rock art complex of the Côa/Portuguese High Douro. The site was later submerged by the Pocinho dam.

In late 1994, during the construction of a new dam in lower Côa River, the first Paleolithic engravings were found at Canada do Inferno, which resulted in a political debate throughout 1995 that resulted in the abdication of the Côa dam.

In 1996, the Parque Arqueológico do Vale do Côa (Côa Valley Archaeological Park) was created to preserve the rock art complex, with an area of *c*. 49,500 acres. In December 1998, the complex was enlisted in UNESCO's World Heritage list, having its statute changed in 2010 through its extension to the Siega Verde complex. In the same year, the Côa Museum was opened.

The establishment of the Centro Nacional de Arte Rupestre (Rock Art National Centre) in 1997 allowed the continuous survey and study of regional rock art. Nowadays there are 72 known sites with 1032 decorated rocks, of which 487 have Paleolithic art (45 sites), 50 have holocenic art (20 sites), 352 have Iron Age art (37 sites), 197 from historic periods (39 sites), and 113 rocks of undetermined chronology (23 sites). Of these, Paleolithic and Iron Age rock art have greater importance being the first world open-air rock art ensemble of the Paleolithic.

Key Issues/Current Debates/Future Directions/Examples

The Côa Valley rock art is mainly engraved (though some is painted) in vertical panels of outcropped schist in the margins of the Côa river and other tributaries until the Douro. The Paleolithic rock art spreads from the Gravettian to late Magdalenian (±26,000 to ± 12,000 BP). The earliest period features a profusion of deep engravings, some of them of great size, and generally superimposed. In the latest period pecking is generally absent, replaced by the almost exclusive use of simple or multiple incisions.

The theme (zoomorphism) is common to both periods, portraying common regional herbivores distributed by four species: Equidae (Fig. 1), Bovidae, Caprinae (Fig. 2), and Cervidae. Rare fish complete this bestiary, to which are added 17 anthropomorphic figures in three rocks, where the ithyphallic anthropomorph of Rock 2 of Piscos is the most known. All these anthropomorphic figures are Magdalenian (Baptista 2009).

The spacial arrangement of the engravings in these two periods differs. The five major sites of the earlier period (Penascosa, Quinta da Barca, Foz de Piscos, Fariseu, Canada do Inferno) are located in the wider areas of the last beaches in the Côa river, whereas the engravings of the later period are concentrated around the Côa river mouth in panels without the abundance of superimposition of the earlier period.

At Fariseu, a great panel (Rock 1) only with engravings of the earliest period (96) was covered with sediments whose deposition started *circa* 20,000 years ago. Absolute chronology demonstrates that the lower part of the panel was already covered *c*. 18,400 years, and a detached piece of the panel was found in this lower layer (Aubry 2009). This dating presents a *post quem* chronology to the engravings of the earliest period, which are stylistically Gravettian. Meanwhile, in this excavation were also discovered 60 schist fragments with linear incision (portable art) (Fig. 3). These incised plaques with small-sized animals and multiple incisions contribute to establish the chronology of stylistically similar engravings found in panels along the Côa valley, since the plaques were found in deposition, most of them in Upper Magdalenian levels (Aubry 2009).

The Second Iron Age is another period of intense engraving, most of them on the Côa river's mouth. The typology of the engravings implies the presence of a hierarchical society, with an almost manorialist caste of warriors. The warriors

Côa Valley Rock Art Sites, Fig. 1 A horse pecked from rock n° 1 of Canada do Inferno (Hell's Canyon). Gravettian period

Côa Valley Rock Art Sites, Fig. 2 Male ibex (capra pyrenaica) with two heads from Quinta da Barca, rock n° 3

are depicted on foot or in horseback, always with their metallic weaponry, spears and javelins, falcatas, and small round shields like those described by Strabo in Geografia da Lusitânia (Lusitania Geography).

There is still plenty of seventeenth- to twentieth-century rock art in the Côa Valley, last remains of an engraving tradition that started at least two hundred fifty centuries ago.

Coben, Lawrence (Larry)

Lawrence S. Coben
Sustainable Preservation Initiative, New York, NY, USA

Brief Biographical Information

Coben has a B.A. in Economics from Yale University, a J.D. from Harvard Law School, and a Ph.D. in Anthropology (Archaeology) from the University of Pennsylvania. He is a University of Pennsylvania–affiliated archaeologist. He is also a member of the Board of Directors of the Bolivian-American Chamber of Commerce and a former golf captain of the Saint Andrew's Golf Club. He served as president of the Board of Directors of New York Stage and Film, a not-for-profit theater company from 1995 to 2003.

Major Accomplishments

Coben's most recent archaeological work focuses on Inca imperial expansion and the role of spectacles, rituals, and theatricality in ancient societies. He coedited the seminal volume *Archaeology of Performance: Theaters of Power, Community, and Politics*, a study of the importance and use of theatrical performance at public events, rituals, and spectacles in ancient societies to create and govern states and empires. He has also written numerous articles on the Inka, sustainable preservation, empires, performance, and complex societies. He has directed or participated in projects in Bolivia, Peru, Guatemala, Ecuador, and Jordan.

Dr. Coben is the founder and executive director of the Sustainable Preservation Initiative ("SPI"). SPI seeks to preserve the world's cultural heritage by providing sustainable economic opportunities to poor communities where endangered archaeological sites are located. SPI believes the best way to preserve cultural heritage is creating or supporting locally owned businesses whose success is tied to that preservation. SPI's grants provide a "two for the price of one" benefit: They create transformative economic opportunities for the local residents while saving archaeological sites for future generations to study and enjoy. SPI is active throughout Latin America, particularly Peru, as well as in Jordan and other countries.

Coben is chairman of ICAHM's Nomination Assistance Committee and vice chairman of its Standards Committee. He was a member of the Governing Board of the Archaeological Institute of America and the first chairman of its Site Preservation Committee. Coben is also a member of the University of Pennsylvania Museum's Director's Council.

Cognitive Archaeology

Antonis Iliopoulos and Lambros Malafouris
Keble College, University of Oxford, Oxford, UK

Introduction and Definition

Cognitive archaeology, or the archaeology of mind, has been broadly defined by Colin Renfrew as the study of past *ways of thinking* through the material remains that have been unearthed (Renfrew 1982, 1993, 1994). Important to note at the outset is that cognitive archaeology does not attempt to identify *what* people thought, but rather *how* they carried out their thinking in interaction with others and the material world. In other words, the archaeology of mind is primarily interested in learning about the different situated processes of human thought as they emerge and take shape in the different cultural trajectories of our species.

The spectrum of abilities that archaeologists have delved into has been wide. Given the position of tools at the starting point of the archaeological record, the technological capacities that were required to manufacture and use them were among the first to be examined. However, it is later-emerging cognitive properties that have received most of the scholarly attention. Symbolism, generally defined as the uniquely human ability to create and manipulate representations, holds a highly prominent place in this context. Language, which is closely tied to symbolism, is yet another ability whose emergence is of the utmost importance for the epitome of the human species and has thus been especially investigated. Despite symbolism and language taking center stage, other capacities, such as abstract reasoning, theory of mind, and self-awareness, have also drawn considerable attention.

The cognitive archaeologist attempts to illuminate the cognitive functions of our ancestors through the construction of inferential frameworks on the basis of present-day evidence. The development of solid inferential steps is often founded on an interdisciplinary approach, within which archaeology plays a vital role. As aptly put by Mithen (1996: 259): "if you wish to know about the mind, do not ask only psychologists and philosophers: make sure you also ask an archaeologist." Given that soft neural tissue does not fossilize, material evidence proves imperative in understanding our cognitive becoming, as it provides the "grounding" upon which the cross-disciplinary narrative can be built. Trying to reconstruct the prehistory of the mind, however, has proved a challenging task, due to the difficulty of establishing testable, empirical, but also culturally sensitive, and philosophically informed links between brain structure, cognitive function, and archaeologically observable behaviors.

Historical Background

In 1956, Vere Gordon Childe argued that an archaeologist must progress from the archaeological material record to behaviors, to thoughts. However, the proponents of the New Archaeology movement that emerged in the 1960s considered the ideational realm inaccessible. This tenet of archaeological thought, also known as "functional–processual archaeology," was characterized by the preoccupation with the *functional* variability of artifacts, rather than the possible

thought processes and categories associated with them (e.g. Binford 1965). Accordingly, prominent figures of the processualist movement, like Lewis Binford (1965: 204), dismissed any exploration beyond the material, into the psyche of past peoples, as unproductive "paleo-psychology."

Despite the initial skepticism, however, the first explicit steps towards the cognitive direction were made during the following decade. Colin Renfrew's study of the role of the "symbolic and projective" subsystems in the emergence of the Aegean civilization (1972) marks possibly the formation of cognitive archaeology (Renfrew 1993: 250). Meanwhile, other scholars had started to accentuate the cognitive capacities required for archaeological artifacts (e.g., Marshak 1972). In fact, according to Kent Flannery and Joyce Marcus (1993: 260), by the early 1970s, archaeologists such as John Fritz and Robert Hall had already listed "cognitive archaeology" among their research interests, in the American Anthropological Association's guide to anthropology departments. Thomas Wynn was the first to adopt a systematically cognitive methodology in studying stone tool use, drawing upon the work of developmental psychologist Jean Piaget. Focusing upon stone artifacts from the Isimila Prehistoric Site, Tanzania, he concluded that Acheulian hominids exhibited organizational abilities characteristic of operational intelligence similar to ours (Wynn 1979). In his 1982 inaugural lecture in Cambridge, entitled *Towards an Archaeology of Mind*, Colin Renfrew outlined the potential of a cognitive approach to the study of the archaeological material record. He argued that questions pertaining to human intelligence are key in describing and explaining the growth and diversity of human societies, which can be recognized as the central goal of archaeology (Renfrew 1982: 2).

In spite of such promising first steps, dubiousness still loomed over the field. As Ian Hodder (1993: 253) informs us, "The term 'cognitive archaeology' or 'the coggies' was used disparagingly in the late 1970s and early 1980s to refer to trends in the discipline which came to be called symbolic, structural, contextual, hermeneutic or interpretive." The tepid standpoint of the functional–processualists seems to have been mainly grounded on their perception that cognitive archaeology deals with the intangible and is preoccupied with mere epiphenomena, such as religion and ideology (Flannery and Marcus 1993: 260). Regardless of such reservations, however, cognitive archaeology continued to develop during the 1980s, admittedly lacking a collectively agreed upon identity and direction, veering off in a number of pathways.

One such line of research, contemporaneous to Anglo-American discourse, arose in France during the latter half of the 1980s, when prehistorians started employing the *chaîne opératoire* approach of André Leroi-Gourhan for the purpose of studying the lithic assemblage. They aimed to illuminate the technology and practical skills (i.e., technique) of the knapper, by methodically interconnecting the lithic assemblage. On this premise, the approach had been used for both technoeconomic studies, which are concerned with the spatiotemporal dynamics of the lithic reduction process, and technopsychological studies, which are focused on conceptual and procedural dynamics. It is the second type of studies that was widely considered to have granted access to the knapper's mind (Bar-Yosef and Van Peer 2009).

In an attempt to establish some common ground, the first conference devoted exclusively to the discipline was organized by Colin Renfrew and Ezra Zubrow in April 1990 at Cambridge. According to Renfrew (1994: 3), the conference marked the passage from "functional–processual" to "cognitive–processual" archaeology; however, it did not appear to yield much consensus, as becomes apparent in the 1993 feature of the *Cambridge Archaeological Journal*, entitled What is cognitive archaeology?. The conference did, nonetheless, spark an increased interest in the cognitive that boomed during the 1990s, as reflected by the number of symposia held in the subsequent years.

The blossoming of the field proved particularly beneficial in attracting the interest of scholars from other disciplines, who drew upon the archaeological record. A beginning was made by cognitive neuroscientist Merlin Donald (1991), who suggested that the mind emerged in three stages: a mimetic skill allowed the transition from the

"episodic" stage of the early hominids to the "mimetic" stage, a linguistic capacity subsequently permitted the transition into the "mythic" stage, and, lastly, writing conferred the transition into the "theoretic" stage. In this last stage, Donald identified a new way of "external symbolic storage." Whereas, up until that point, neural engrams had been relied upon for the purpose of storing memories, novel material media provided humans with the ability to store information that could be retrieved at a later date, thus instigating a radical change, not only in the capacity, but also in the operationalization of memory. The increasingly expanding list of such exograms has ranged from hieroglyphs and writing systems to diagrams and decorations. In this light, biologically molded human beings had been coupled with material culture in order to transition into a biocultural hybrid phase. Another noteworthy work by a scholar external to the field was authored by biological anthropologist Terrence Deacon (1997), who used a triptych of signification proposed by semiotician Charles Sanders Peirce (i.e., icons, indexes, and symbols) as a cornerstone, in order to put forth an account of the emergence of linguistic symboling. By constructing a nested hierarchy, with icons at the bottom and symbols at the top, he associated each level of reference with its own degree of consciousness and underlined that humans are the sole species possessing symbolic consciousness, for they moved from indexes, which are characterized by associative learning, to symbolism, based upon "a change in mnemonic strategy, a recoding" (Deacon 1997: 89).

The 1990s also saw the first cross-disciplinary collaborations, such as that between psychologist William Noble and archaeologist Iain Davidson, who advocated that it was the emergence of language that yielded the "modern" mind, for as they put it "'the mental' equates to language in human life" (1996: 226). Their view, in brief, is that pointing gestures would occasionally be captured in plastic media, such as mud, becoming thus signs vulnerable to further manipulation and open to arbitrariness, as any vocal accompaniments of the gestures would be transformed into linguistic symbols, therefore birthing a "modern" type of language.

The prospering of cognitive archaeology continued well into the new millennium, with a number of agendas, purporting to account for the emergence of "modernity," sprouting into existence.

For one of these schools of thought, the unearthed material evidence was the outcome of a genetic mutation. Paleoanthropologist Richard Klein (2009) has famously advocated in support of a fortuitous mutation in the executive brain, which he suggested granted humans a qualitative neural advance. He claims that prior to 50 kya, morphology and behavior appeared to have evolved relatively slowly, whereas after this time, behavioral change accelerated rapidly, while morphology remained relatively stable (Klein 2009: 745). Along similar lines, anthropologist Thomas Wynn and psychologist Frederick Coolidge (2011) have identified an additive genetic mutation that enhanced our working memory capacity, as one of the final components of the "modern" mind. An increased ability to retain and process information in active attention is beneficial for a wide range of essential cognitive capacities, such as fluid and general intelligence, and linguistic comprehension, acquisition, and expression. Based on their interpretation of the archaeological record, they determine the mutation to have certainly been in place by 30 kya and perhaps as early as 77 kya.

In another account of mental evolution, Iain Davidson (2010) has supported a modular mental model based on a concept put forth by neuroscientist Philip Barnard, according to which information flows through a number of interacting cognitive subsystems. The framework purports that humans have evolved from species with fewer subsystems to possess a nine-subsystem model of cognitive function, with each system specialized in a specific type of representation.

Archaeologist Miriam Haidle (2012) attempted to delve into the cognitive lives of past peoples by developing and employing yet another distinct investigative technique. The essence of her approach rests in identifying the thought-and-action processes required for the manufacture and use of tools. This is done by

coding the physical actions required for tool construction into a sequence of operational units depicted in a "cognigram."

A final contemporary doctrine was fathered by Colin Renfrew, who switched gears in 2001, by imbuing material culture with a more "active" role, at the expense of its, until that point, reduction to an epiphenomenal product of the mind. By highlighting the implications of human *engagement* with the material world, he set the foundations for a cardinal transition that transformed the discipline. He dismissed the mind/matter dichotomy, adopting a *hypostatic* approach, according to which the mind's symbolic capacity emerged via praxis in the material world (Renfrew 2001: 128–29). It is in the light of such a process of "substantialization" that symbolic concepts and their material manifestations arose in unison. Adopting these theoretical underpinnings, cognitive archaeologist Lambros Malafouris (2004) drew extensively from philosophy of mind, in order to illuminate the pitfalls of the commonly adopted Cartesian methodological individualism, and identified the cognitive system as embodied, mediated, distributed, and extended. Archaeologist Carl Knappett (2005) shared this notion of the mind and contextualized its realization in non-anthropocentric interactive networks whose nodes are constituted by inextricably tied brains, bodies, and artifacts. Bidirectionality of agency between the nodes is a pivotal principle characterizing the networks, for while it is action that creates and reshapes material forms, it is also action that is exerted by them. It is in precisely such a cognitive landscape that humans act and think through material culture (Knappett 2005), as well as create and reproduce their identities (Gamble 2007). In moving away from the exclusive preoccupation with the representational, what emerged is the ability of humans to self-engineer themselves through the physicality of their agency-bearing material worlds (Boivin 2008). However, one's cognitive and existential manifestation is shaped not only by material culture but also by neighboring embodied brains. Hence, to refer to this network-born entity, archaeologist Chris Gosden (2008: 2003) advanced the "notion of a social ontology, which holds that human life unfolds through an equal input from materials and from people."

But how does this discussion on the cognitive translate into biological terms? What is the relationship between the human neural apparatus and the unearthed material culture? In seeking answers to such questions, archaeologists turned for enlightenment to neuroscience – a field with visual access into the functioning brain, permitted by recent advances in neuroimaging technology, such as functional magnetic resonance imaging (fMRI). Recognizing the benefits of incorporating such knowledge into the study of the past, Lambros Malafouris and Colin Renfrew (2008) were among the first to systematically bridge the fields of neuroscience and archaeology, yielding an integrated theoretical platform they termed "neuroarchaeology." It is encouraging to note that, at this time, cognitive archaeologists also started harvesting the potential of imaging techniques more directly by conducting neuroarchaeological experiments. For example, positron emission tomography (PET) was used to monitor the functional brain activation during the experimental manufacture of Oldowan and Acheulian tools by experts (Stout et al. 2008). Interestingly, the observed patterns of activation overlapped with the neural circuits employed by language, possibly suggesting mutually reinforcing coevolution.

In concluding this brief historical overview, it should be acknowledged that the cognitive capacities possessed by the Neanderthals have also received a moderate amount of attention in the past decade or so. For instance, Thomas Wynn and Frederick Coolidge (2004) argued that their working memory capacity was lower than that of their anatomically modern counterparts, granting them with a smaller phonological store, or a reduced attention capacity. While symbolic reference does not depend on working memory, the authors purported that the reduced capacity of the Neanderthals would have constrained the number of symbols they would have been able to process and that their language must thus have been more laconic compared to the richer version used by anatomically modern humans.

Key Issues/Current Debates

Questions concerning the origins of "modernity" have been at the forefront of paleoanthropology and cognitive archaeology ever since the publication, in 1989, of *The Human Revolution*, a volume edited by archaeologist Paul Mellars and anthropologist Chris Stringer. "Modern human behavior" is an ambiguous and much contested term (Shea 2011), which has nevertheless been widely established as referring to a "package" of behaviors considered to characterize the uniqueness of the "modern" human condition. Not surprisingly, symbolism and language are unambiguously considered the most important elements of this bundle. Nevertheless, despite agreement upon the behaviors of primary importance, the spatiotemporal scenarios that have been purported to explain the crossing of the Rubicon towards "behavioral modernity" remain much contested (for a good review, see McBrearty and Brooks 2000; d'Errico and Stringer 2011).

Similarly, a variety of mechanisms have thus far been considered as the instigators of the transition towards "modern human behavior." An overview of the literature will reveal that scholars are roughly divided into two broad and heterogeneous schools of thought. Some emphasize sociodemographic factors, such as the increasing population density, as the prime mover of behavioral change, due to its indubitable effect on chances of innovation. Others see the emergence of a "modern" mind as the prime mover of increasingly complex behavior. Their preoccupation with our cognitive evolution has indeed contributed much in demonstrating the primacy of the mind in explaining the origins of "behavioral modernity."

Dissonance among these scholars in their conceptualization of the directionality between human mind–material culture interactions requires a further dichotomization of agendas into representationalism and interactionism. Pondering along the lines of "the chicken or the egg" causality dilemma, did the brain mold the unearthed artifacts, did the latter mold the former, or is the relationship between them best seen as bidirectional? Answering this question primarily rests on an archaeologist's disposition of *where* the mental resides and *how* it unfolds – issues that dwell well within the territory of philosophy of mind.

According to the representational or internalist idiom, preexisting concepts were initially formed within the mind, before being materialized in objects through action. This dualistic disposition is still much alive today with many scholars implicitly or explicitly subscribing to the computational view of a mind receiving and processing external sensory stimuli "trapped" within the cranial cavity.

A rejection of the representational view can perhaps be traced back to the mid-1990s, when William Noble and Iain Davidson (1996) argued in favor of what they termed a "social construct" model of the mind, which posits a conception of the mind as socially distributed. An implication of such view is that universal conclusions about past minds cannot be drawn, for as has been suggested by prominent post-processualist Ian Hodder (1993), if all aspects of cognition are partly social, then interpreting social meanings and contexts is the only way to study cognition with respect to particular societies. However, this emphasis on contextual interpretation was not entirely without problems. For instance, cognitive archaeologists, such as Kent Flannery and Joyce Marcus (1993) and Colin Renfrew (1993, 1994, 1998), failed to recognize the multi-faceted nature of cognition, largely equating the "cognitive" with the "symbolic" and therefore placing symbolic material culture at the forefront of the discipline. Such an extensive preoccupation with the symbolic, however, has been critiqued by Carl Knappett (2005) for disregarding non-symbolic forms of embodied intelligence, which should also be taken into consideration. Moreover, early studies in cognitive and symbolic archaeology failed to appropriately define symbolism (Knappett 2005; Preucel 2006). While acknowledging the fundamental role of symbolism for signification, they omitted recognizing that, along with symbolic action, it also required pragmatic action. Hence, although communication and signification can overlap, early scholars failed to comprehend that they are not required to do so.

At the turn of the millennium, however, cognitive archaeology apparently came of age with a variety of theoretical advances which challenged the consensus' view of the mind as an internal processor, by introducing an externalist perspective that highlighted the "active" role of material culture in bringing forth the mental (e.g., Renfrew 2001; Malafouris 2004, 2013; Knappett 2005; Boivin 2008; Gosden 2008). This enactive relational stance required the radical rethinking of both the material and the neural ends of the interaction – the plasticity of which allowed them to be concomitantly molded via a constitutive intertwining of brains, bodies, and things that enabled the cognitive to unfold, in real time and space, unhindered by cranium- or skin-delineated boundaries (see esp. Malafouris 2013). For cultural neuroscience has proved beyond doubt that cultural phenomena can lead to an extended structural and functional reorganization of our brain's architecture permitted by its extremely plastic nature. Thus, the cognizing neural apparatus of our anatomically modern human ancestors appears to have been in fact sculpted into a "modern" mind upon engagement with material culture – a conclusion which appears to account for what Colin Renfrew termed the "sapient paradox": "if the biological basis of our species has been established perhaps for as much as 200,000 years, then why have the novel behavioural aspects of our 'sapient' status taken so long to emerge?" (Renfrew et al. 2008: 1935).

Future Directions

Despite the fact that our cultural trajectories have been solidly described and are constantly enriched by additional discoveries, there is still much to be learned about the origins of our cognitive ontology. Hence, the emergent, at this point, question is: How should the cognitive sphere of past peoples be approached?

It must be recognized that the feasibility of the field's aspirations has much to gain from interdisciplinarity. Cognitive archaeology has been demonstrating remarkable progress, mainly due to transgressing the traditional borders that isolated it from other disciplines and incorporating their sagacity, yielding thus an interdisciplinary research program that aims at answering broader questions on the emergence of the human mind. As would be expected, the synergistic fusion of the composing disciplines required a point of intersection that fell beyond archaeology itself, maintaining, in the meanwhile, the general analytic objective of cognitive–processual archaeology – namely, using archaeological material remains in order to understand past ways of thinking as they emerge and take shape in different evolutionary and cultural trajectories. Neuroarchaeology is a fine example of a collaborative synthesis whose yield has thus far been particularly fruitful, despite still being at an early stage. While it can offer invaluable insight for the pre-sapiens period of the evolutionary trajectory, its analytic potential can mainly be harvested by scholars examining the period following the so-called speciation phase, due to its implementation of findings made by disciplines focused on anatomically modern humans. Archaeologists have indeed learned much about the biological, social, and cultural foundations of the human mind by working with anthropologists, philosophers, neuroscientists, and social and cognitive scientists. Reciprocally, cognitive archaeology, probably more than any other field of cognitive research, has granted the material world with laudable value for its essential role in impelling and shaping the mental.

On this note, it is time we overcome, once and for all, the "representational fallacy" pervading much contemporary work, for material culture is much more than a mere epiphenomenal product of a brain-residing "ghost in the machine." Our Cartesian spectacles should be left behind, opting instead for a fluid view of a sapient mind emerging from the bidirectional coalitions between brains, bodies, and things (Malafouris and Renfrew 2010; Malafouris 2013). For as has been stated by Chris Gosden (2008: 2010): "The complex actions and interactions of brains, bodies and worlds are what make us human and historical." The introduction of such a radical, for the consensus, outlook in our attempt to trace our cognitive becoming will allow us to better comprehend the concomitant molding

of both the neural and material components of this symbiotic triad. It is hence of paramount significance that we fully appreciate the process of redesigning ourselves through our embodied engagement with the scaffolding provided by material culture. By being committed to such a relational, rather than reductionist, view of the mind, we evade falling into the trap of neurocentrism and thus avoid mistaking the properties of the sociocultural system for the properties of the individual or the brain (Hutchins 1995). For we should constantly remind ourselves that disregarding the "active" role of material culture is a rather inexcusable error by the discipline that prides itself on studying things from the past.

Cognitive Evolution and Origins of Language and Speech

Iain Davidson

Faculty of Arts and Sciences, School of Humanities, University of New England, Armidale, NSW, Australia

Introduction

The archaeological study of cognitive evolution is closely related to the study of the origins of speech and language. The two issues are related as a result of (1) the general nature of any form of communication and (2) the special nature of human communication. First, in general, all communication has an emitter, a receiver, and a message. In most cases, the emitter and the receiver are tuned to each other's communications, and there is little problem in sending or receiving the message. In all organisms other than humans, there are questions about the intentional control of the messages that can be sent. Intentional communications require different cognition from

those that arise without thought. Second, in the special case of humans, we have a peculiarly complex form of emitting sounds and an auditory system well tuned to hear those sounds. In almost all circumstances, humans are capable of controlling the information they communicate to another person, which can be called the meaning of the message. Control of such meanings is a cognitive difference between humans and most (if not all) other animals. The problem for the study of both issues is to relate them to the material record available to archaeology.

To those of us used to reading the written or printed version of such sounds, it seems straightforward that someone speaks words and that we hear them, but recognizing this message requires an unconscious separation of the sound stream into smaller units (corresponding to the gaps between words when written on the page). Such words can have different meanings for different people because they are determined among communities of speakers by convention and generally bear little relation to the things they refer to. Because of this property of "arbitrariness restricted by convention," all words are symbols.

This complex system is very different from the relatively restricted range of utterances by apes and the apparently limited range of things that they can communicate. The evolutionary emergence of these differences involved changes in the system for production of sounds, in the auditory complex that hears those sounds, and in cognition that relates sounds to meanings. In addition, uniquely among humans, the meanings that can be conveyed in speech can also be conveyed in sign languages based on manual gestures and, as you see, in the written word. Several scholars have argued that symbolic communication using manual gestures may have preceded spoken language.

Finally, humans appear to be unique in the capacity to combine individual utterances into combinations according to sets of rules, known as syntax, such that they can utter an infinite number of sentences composed of a smaller number of words. Except in circumstances of serious pathology (including deafness), or of extraordinary deprivation of exposure to language during the early years of life, the expectation is that humans are able to learn language and use it to communicate with others. Among deaf people, language can be transmitted using Sign Languages (which differ from community to community as spoken languages do).

These complexities mean that there are many false pathways for investigating the evolution of cognition and the origins of language and relating to the relative importance of the different elements of speech, syntax, or the cognitive apparatus that supports them. These false pathways seem to offer understanding, but actually cause confusion.

Definition

Evolution

Evolution is a process by which the characteristics of populations change through the operation of natural selection on the inherited variable characteristics of individuals. It is important to remember that most of the variation arises by chance from one generation to the next, and most of the selection operates to eliminate variations. The logic of this formulation is that new characters within the variation should appear at low frequency within a population and subsequently become important due to selection.

The discussion of evolution is often undertaken with misleading metaphors that allow people to believe that there is either a direction to evolution or a force driving it. There is no direction (except seen from the present position) and no forces driving evolution.

Cognition

By a classic definition (Miller 1956), the aim of cognitive science is to: "discover the representational and computational capacities of the human mind and their structural and functional realization in the human brain." The evolution of cognition, therefore, must be studied through the evidence of changes in such representational and computational capacities and the limited evidence of the workings of the mind, first from the evidence of behavior (as is the practice of psychologists of the living) and second from the shadowy

traces of the brains of human ancestors (for a summary of this process, see Davidson 2010a). Such evolutionary studies necessarily require the interpretation of the evidence of behavior from archaeological remains. Any inferences about cognition require well-constructed theory about the relationships between elements within the neurological system, the mental system, and the behavioral system as well as theory about the relationships between these different systems (Barnard 2010). Inferences about the evolution of cognition require all of these together with a clear argument about the relations between these elements and the archaeological record (see, e.g., Botha 2010).

The Brain of Humans and Their Ancestors

There are three relevant issues about the brain: (1) size, (2) localization of specific functions to specific areas of the brain, and (3) evidence from genomics about the genetics of brain function and its history.

The easiest is the size of the brain. Among modern humans, the size range is 1,000–1,700 ml (Lieberman 2011: 192–195). The fossil record shows that the cranial capacity (only an approximation for brain size) of the last common ancestor of about 400 ml was much closer to that of modern apes than to that of modern humans. There are substantial data on the increases in cranial capacity in two steps: one at about two million years ago to a maximum around 1,000 ml, accompanied by a change in body size, and the other between 0.4 and 0.2 million years that was not accompanied by significant change in body size. Each of these changes was followed by the extinction of the creatures with the lowest range of cranial capacity, first those below 700 ml and then those below 1,000 ml (see, e.g., Davidson 2007). The estimates of cranial capacity of fossils are rarely precise, and the relevant fossils often have uncertain dating. It has been argued that brain size is closely related to group size as a means of solving the problem of living in large, complex groupings (Dunbar and Shultz 2007), but some of the key elements of the argument have been shown to be unreliable (Davidson 1999).

As regards the specific functions of regions of the brain (there is an accessible discussion of the main features of this in Coolidge and Wynn 2009), language deficits caused by traumatic damage were the original source of understanding that Broca's area is associated with language production. Subsequent work showed similar associations with specific language features (e.g., Wernicke's area with language comprehension) or aspects of cognition (such as the loss of executive function following catastrophic injury to the frontal lobes). There is no doubt that in ordinary circumstances, particular regions of the brain are associated with particular functions, but the advent of brain imaging of various sorts has shown that functions are distributed more widely in the brain (see, e.g., many PET scan results in Deacon 1997: Chap 10). In addition, recovery of function following stroke or some other massive insult to the brain suggests that the brain is more plastic than sometimes suggested (e.g., Cramer 2008).

Other work has described changes in the morphology of the interior cavity of the skull as represented by the endocasts of the brain or by computed tomography (Bruner 2008). Notably, differences between the endocasts of Australopithecines and early *Homo* have been interpreted as indicating the earliest appearance of Broca's area (Falk 1983), but more recent comparisons with other primates make the interpretation of this more difficult (Schenker et al. 2009). A case can be made that there has been selection for regions such as the basal ganglia and the cerebellum, which are associated with procedural learning, and for hierarchization of the different regions of the brain (Gibson and Jessee 1999).

Language

Because in normal circumstances humans use language, it is easy to avoid definition of the concept – we know what we are doing when we use it, the argument goes. This is another cause of confusion in discussions of its evolution because people have different informal understandings of what is involved. When examining the archaeological record, the definition needs to be one that can be operationalized with nothing more than the

fragmentary things found there. Without a definition of this kind, it is impossible to choose between hypotheses that are products of different theories about the nature of modern language. Nevertheless, most definitions recognize that the basic elements of language are symbols (see, e.g., the discussion in Crystal 1987: Sect. 64).

Some others restrict the definition of language by requiring rules about the combination of such symbols using syntax or grammar. For the purposes of archaeology, it is convenient to define language as communication using symbols (Noble and Davidson 1996) and consider as a separate issue how such symbolic communication came to have rules about combinations.

Speech

At the very beginning of serious study of linguistics, Saussure recognized that the relationship between speech and language was complex, since, in the ordinary course of events, speech does not exist separately from language, yet conceptually the two aspects of the single phenomenon are different (Saussure 1986). Speech can be defined as: "A set of audible sounds produced by disturbing the air through the integrated movements of certain groups of anatomical structures. Humans attach symbolic values to these sounds for communication" (http://www.answers.com/topic/speech downloaded 23 November 2012 10.35 am). Much of the bodily apparatus for producing these streams of air consists of soft tissue and is therefore difficult, but not impossible, to study through skeletal remains. Many examples have been shown not to reveal as much as was hoped about the emergence of speech production (summarized in Davidson 2003: Table 8.1), but more recent studies have claimed that skeletal evidence dated to about 0.5 Ma ago from Atapuerca, in Spain, demonstrates that the bones of the outer and middle ears allowed them sound power transmission into frequency ranges higher than those available to chimpanzees, but with upper limits lower than those of present-day people (Martínez et al. 2012).

The separateness of speech and language is important in the study of both cognitive evolution and language origins. First, as with other vocal utterances by primates, it is possible for hominins to have produced sounds without symbolic meanings attaching to them. Selection could have operated on variations in the anatomy for production of sounds and the concomitant anatomy for hearing without the meanings associated with those sounds being symbolic. Second, if we go by ape sound production, there were substantial cognitive changes required to go from what Burling (1993) called relatively involuntary "gesture calls" to the state where the hominin making the sounds had human-like control of the subtle ranges of sounds humans can make. Third, Saussure recognized that speech and language were inseparable in practice and that the study of linguistics involved the study of the signs involved in the meanings conveyed by language. While those meanings require a social community of speakers, they must also have been a novel product of the cognition of the individual speakers.

Semiotics

The study of signs is called semiotics. A sign was defined by Peirce (1986) as "something which stand[s] to somebody for something in some respect of capacity." To put Peirce's analysis simply, three classes of sign are fundamental: indexical signs, iconic signs, and symbolic signs. According to Peirce "an *Index* is a sign which refers to an Object that it denotes by virtue of being really affected by that Object." The standard example is smoke as an indexical sign of fire, but a less ephemeral example is the footprint left by a person walking on volcanic ash or mud (as at Laetoli or Lake Mungo). All pieces of archaeological evidence are indexical signs of past behavior. Indexical signs are overwhelmingly abundant, but interpreting them is not always obvious (or archaeologists would not need to be trained). Indexical sounds that may be related to the production of vocal communication are grunts in young children or "exclamatory words of high emotion" (Jackendoff 1999), although these are generally not as spontaneous as they seem (Davidson 2005).

Peirce's (1986) definition of iconic signs is: "A sign may be iconic, that is, may represent its object mainly by its similarity. . .." The concept

is familiar through the generalized resemblance between the images in religious icons and a human figure; though this example illustrates that the similarity between icon and object may take many forms – the religious icon represents a generalized human being, but an iconic representation of recognizable individuals is a different sort of achievement. In vocal communication, onomatopoeic utterances are generally iconic, but, as with indexical utterance, they also are constrained by the conventions of the speaker's language. Iconic gestures are not unknown among apes. Burling (1999) has gone further and suggested that the sequential structuring of syntax has elements of iconicity to it. In sign languages, many utterances become conventionalized from iconic gestures and hence are symbols, but such utterances may also be indexical signs (Stokoe 2000).

Peirce discussed symbols in several different ways, but that which is formulated in a manner most similar to the standard "signs that are both arbitrary and conventional" seems to be that symbols are signs that "represent their objects, independently alike of any resemblance or any real connection, because dispositions or factitious habits of their interpreters insure their being so understood" (quoted in Nöth 2010). The importance of symbols for the archaeological study of language origins (and hence cognitive evolution) is that there is some chance that material objects may be identified as symbolic in the archaeological record, but care must be taken with the way in which that is done.

Learning

Language learning is social and there is absolutely no parallel in nonhumans. In all cases, language is the usual means of communication among humans and only present among other free-living animal species by stretching the definitions of language (see, e.g., extensive discussions in Davidson 1999).

Language is learned by very young infants at their mothers' breasts. In particular, small babies, carried in their mothers' arms in front of them, learn to attend to those things their mothers notice (see the argument in Noble and Davidson 1996). This provides the circumstances for selection for learning. The key trigger for infant carrying and hence the joint attention that promoted infant learning was the emergence of obligatory bipedal walking – present by 3.5 Ma ago, as shown by the Laetoli footprints – and hence front carrying.

The emergence of prolonged infant dependency and the life history pattern of modern humans were essential for humans to go through all of the stages of learning (for a general summary of life history variables and their relevance to archaeology, see Nowell in press). When compared with other primates, human infants have a much longer period after birth during which their brains continue to grow at the fetal rate, and they have to be carried for most of their first year of life. Learning and symbol use are not simply a product of brain changes, but of the social context (Noble and Davidson 1996).

Historical Background

Arguments about cognitive evolution and the origins of language and speech have historically depended on a few consistent lines of inquiry. Five such approaches derive from (1) knowledge of modern languages, (2) understanding communication among nonhumans, (3) the anatomical basis of speech production and reception, (4) archaeological evidence for symbol use, (5) and the recognition that language and human cognition can be understood in the context of evolutionary argument.

First, discussion about the origins of language depended on speculations about modern languages, to the extent that the Linguistics Society of Paris famously banned such discussions in 1866. More recently, Chomsky claimed that language was too complex to be explained by evolution. Much recent work has returned to the examination of languages, initially by looking at pidgins as examples of protolanguage (Bickerton 2007) (although pidgins only exist when full modern languages are in contact). More recently, progress has been made by considering meaning making in an evolutionary framework by careful assessment of the differences between human and

animal conceptualization (Hurford 2007). Arguments based on modern languages are unlikely to reveal much about the initial conditions of language production except through such cognitive analysis.

Second, research has been undertaken into the communication of nonhumans, especially landmark studies of the so-called alarm calls of vervet monkeys in the wild (Cheney and Seyfarth 1990), extending to attempts to devise methods for two-way communication between humans and captive apes (Savage-Rumbaugh et al. 1998). The monkey work showed that the communications were relatively unlike language in the limited nature of the utterances and the very specific contexts in which they were used. The ape work showed that comprehension might exceed production, that learning might best be done spontaneously without instruction in a social context, and that language might best be considered not as something that the apes learned as individuals, but that language-like communication came to exist in specific ape-human interactions. Language was shown to be a property of the relationship not of the individuals involved. The most important conclusion from the study of nonhuman primates is that there are such cognitive differences between modern apes and humans that their last common ancestor seems likely to have been cognitively different from modern humans.

Third, in the hope of finding real evidence from the past, attention shifted to the anatomical correlates of speech production either in the throat (for a recent reassessment of work going back to the 1970s, see Lieberman 2007) or in the brain (for a similar reflective history, see Holloway 2008). The investigation of speech drew attention to the need to consider carefully the relationship between speech and language, as well as the question of what speech abilities might have been a necessity for adequate use of language. New discoveries allowed the analysis of breathing control among extinct hominins (Maclarnon and Hewitt 2004) and of their hearing (Martinez et al. 2004). The brain studies led to a more careful consideration of the relations between speech production as a motor function (control of musculature) and as a mental phenomenon. Such studies show that there has been biological evolution of anatomical structures that make modern speech possible, and some of what those evolutionary changes were.

Fourth, archaeologists began to realize that they might have something to say on the matter (Dibble 1989), particularly when the emphasis in defining language shifted to symbols rather than syntax (Davidson and Noble 1989) and the recognition that the claims for early symbol use were less secure than it had seemed (Chase and Dibble 1987). Collaboration of archaeologists with psychologists and cognitive scientists demonstrated that much more subtle inferences were possible if appropriate theory was developed (Noble and Davidson 1996; Coolidge and Wynn 2005; Barnard et al. 2007). Archaeology remains one of the few sources of information about the past which can tie past behavior to particular times and places. Making inferences about cognition or language from such behavioral evidence requires the specification of theoretical links.

Finally, a key paper by psychologists argued strongly that language could be analyzed in an evolutionary framework, allowing linguists to contemplate its origins (Pinker and Bloom 1990). This ultimately led to Chomsky being involved in an attempt to look at evolutionary aspects of language and the claim that the most significant novelty of language was the capacity for recursion (Hauser et al. 2002). Depending how recursion is defined, there is some potential, largely unrealized, for the identification of recursion in the archaeological record (Coolidge et al. 2010).

The outcome has been an outpouring of research on language origins since 1989 taking advantage of all of these developments (for a wide ranging review of the literature see Johansson 2005). In addition, through the multidisciplinary interaction, there emerged a consensus that some of the avenues of inquiry did not relate closely to the concerns of linguists, except insofar as both required the emergence of particular cognitive abilities. In this way, evolution of cognition and origins of language became closely related in research programs.

Key Issues/Current Debates

There were two relatively early attempts to look at the archaeological evidence for cognitive evolution. The first (Holloway 1969) was a logical extension of the author's interest in brain processes and considered the content of knapping actions both in terms of their semiotic significance and in relation to the possibility that sequential actions in the production of finished artifacts had some parallel with syntax. The second was a sustained, and pioneering, effort by Wynn to apply to artifacts of the early stages of hominin evolution the spatial concepts Piaget discerned as defining the cognitive abilities emerging at different stages of human ontogeny (summarized in Wynn 1999). Wynn has subsequently moved beyond this analysis and, particularly, has worked with cognitive scientist, Coolidge, to show the role of Working Memory in Neandertals and modern humans (an accessible work that summarizes many papers and a book is Wynn and Coolidge 2012).

In addition, Wynn has revisited a comparison between the behaviors of chimpanzees and early hominins to conclude that chimpanzees seem more similar to a human ancestor, but at the same time, those human ancestors seem more like apes (Wynn et al. 2011). These coauthors identified that both apes and the earliest hominins lacked "curated tools intended for repeated future use; shape imposition and shared standards for shape; semiotic load, or the use of tools to communicate information about the tool user to other tool users; linguistic instruction for tool fabrication." All knapping produced indexical signs of the act (the flakes not removed from the site) and these undoubtedly provided the opportunity for other hominins to notice novel signs of activity (Davidson and McGrew 2005). It is an unsolved question when hominins first identified that semiotic novelty. Such an argument is related to, but different from, suggestions that interaction between humans and external material culture was an important element of the expansion of human cognition (Donald 1991; Schiffer 1999).

The problem with both the use of Piaget and of Working Memory theory is that the viability of the interpretation depends on the way in which you interpret the archaeological record, and these cognitive theories do not offer much guidance. No one has seen a Working Memory, and whether it has a location in the brain is a matter of controversy. It is, rather, identified by a number of more fundamental behavioral features said to characterize it. In one analysis relating to the first colonization of Australia (which has only ever been populated by modern people), it proved far from straightforward that even basic markers of Working Memory could be identified (Davidson 2010d). More work will be needed to deal with this issue and to specify how the Working Memory model might need to be modified to be useful in describing the behavior of non-modern people.

Cognitive Novelties of Humans

Byrne (2004) compared the abilities of apes with those required to make early stone tools. He pointed out that to make stone tools requires "accurate aiming of powerful blows. . .bimanual role differentiation. . .regular and sequential plan. . .hierarchical organization. . .corrective guidance by anticipatory schema. . .high individual manual laterality and population right handedness." His conclusion was that, among the African apes, hierarchical organization had been observed among gorillas, but not unequivocally among chimpanzees (though this may be a problem of the research). Corrective guidance by a schema has not been observed in either species, and population right handedness has been observed in gorillas but not in chimpanzees (but individual handedness has). All other features can be identified in all species of African ape. On the other hand, cutting appears to be absent from apes in the wild but must have been a principal motivation for the deliberate production of stone flakes from the very beginning (Davidson and McGrew 2005).

Amati and Shallice (2007) listed a variety of cognitive capacities of modern humans that contrast with those of animals. These were the following: (1) language; (2) tools and instruments that go beyond those used by other primates; (3) signs, signals, and other homomorphic representations; (4) dynamic concepts; (5) aesthetic

sense; (6) metarepresentation; (7) algorithmic capacity; (8) categorization and organization; (9) theory of mind; and (10) anticipatory planning. There are three important points about such a list. First, not all of the capacities are completely independent of each other: several probably depend on the prior emergence of language. Second, animal ethologists, particularly primatologists, would argue that there are hints of several of these capacities in one or other species of nonhuman or that there has just not been enough research on particular species to be definitive about the absence of such capacity (Boesch 2012). Third, expressed in these terms, some of these capacities are difficult to identify either in the archaeological record or by any other form of evidence or argument.

An earlier attempt to define the cognitive properties of modern human behavior identified complex information exchange, planning depth, and symbolic conceptualization (Noble and Davidson 1991) which could be operationalized in terms of a relatively small number of traits manifest in the archaeological record. Those traits, somewhat divorced from their cognitive context, were expanded and codified to show that cognitive change probably happened gradually and not exclusively in Europe (McBrearty and Brooks 2000). Further investigation has shown that not all of the elements of that list of traits need be present to identify the presence of modern human behavior (Davidson 2010d): the true mark of modern human cognition is flexibility.

Barnard and Byrne developed a theoretical model that could account for the evolutionary changes in cognition. Barnard originally produced a model of present-day human cognition that has 9 subsystems as an elaboration to overcome deficiencies in the Working Memory model of human cognition (Barnard 1998). Capitalizing on Byrne's familiarity with ape cognition (e.g., Byrne 1995) and Barnard's model, it has been shown that ape cognition can be modelled with six of the nine subsystems, making it likely that there are or were creatures with seven and eight subsystems (Barnard et al. 2007), in all likelihood represented only by extinct hominins.

Among the six subsystems required to account for the known technical abilities of apes, complex hand-eye coordination evolved early in the sequence as a difference from the common ancestor with (5-subsystem cognition) monkeys. In keeping with the observations of Wynn and colleagues and of Byrne, this level of complexity probably characterized the earliest stone tool makers. Complex coordination of vocal utterances in response to visual stimuli would have emerged in the 8-subsystem framework. Language, involving reflective awareness and the expression of thoughts unrelated to external stimuli, emerged only with the emergence of the ninth subsystem.

One element of the argument is an appeal to linguistic theory about semantic roles as a way forward to identify the similarities and differences among humans, hominins, and apes (Byrne et al. 2004; Davidson and McGrew 2005). In this analysis, it is suggested that the statistical regularities of roles that are made salient by the persistence of the stone artifacts as material remains could have enhanced the perception of the semanticity of the actions of hominins. Something similar may apply in the case of mark making that became pictures, with the important difference that several of the supposed semantic roles require some mental processing which could only be done with the ninth subsystem in the Barnard model (Davidson 2012a) (see Table 1).

One implication of this model is that it may be that premodern people were able to communicate with speech that did not use symbols but was nevertheless structured in complex ways similar to syntax. Under these circumstances, adults could have assisted the learning of their offspring by spoken utterances that were not yet language (Davidson 2009). The further implication is that the nature of the interactions involved in the production of symbolic objects implies the appearance of the ninth subsystem in the Barnard model – i.e., fully modern cognition. One of the future challenges for the study of cognitive evolution is to relate the 7- and 8-subsystem models to the evidence from the archaeological record.

Related to the question of semantic roles is the whole question of whether the primitive elements

Cognitive Evolution and Origins of Language and Speech, Table 1 Semantic roles implied by chimpanzee behavior, stone tool making and by picture making

Semantic role	Chimpanzee semantic roles (from Byrne et al. 2004)	Stone tool making (Davidson and McGrew 2005)	Picture-making (Davidson in press)
Agent	Chimpanzee Mike climbs a tree	Lucy fetched the stone	Pablo fetched the ochre
Counter-agent	A chimpanzee strikes a fruit against a stone to open it	Lucy hit the stone with a rock	Pablo rubbed the ochre on a rock
Object	Chimpanzee Figan is now an alpha male	The stone breaks	The ochre marks the rock
Result	Chimpanzee makes a fishing probe	Lucy made a flake	Pablo made a mark
Instrument	Spherical stone used as a hammer to crack nuts	The flake cut the carcase	*The mark made me think of a camel*
Dative	Female chimpanzee Flora is being groomed	*I gave the meat to Lucy*	*Pablo told a story about a camel to me*
Experiencer	*Waa* barks show that Frodo is angry	*Lucy felt well-fed*	*Pablo and I knew some things about camels*
Locative	A group of chimpanzees goes to the group's periphery to look for intruders	Lucy walked away from the flake scatter	*Pablo remembered this as the place of the story of the picture of the camel*

of language were individual words or were more holistic (Wray 2002), an argument that is more persuasive given the abundant evidence from the earliest written language that the dominant process of language change has been simplification and trimming (Deutscher 2005). Even if the earliest elements of language were not individual words but holistic phrases, they would still have had symbolic meaning by convention and been arbitrarily related to their referents. So the issue remains: how can we identify the symbolic content of the archaeological record as a guide to cognition and language?

Symbols and Other Signs

Cultural artifacts acquired meaning first as indexical signs – they were consistently associated with particular situations or conditions. Thus, the debris left from flaking episodes could be seen by the knapper or by other hominins as a sign that knapping had taken place there previously (Davidson and McGrew 2005). Most artifacts have forms that resulted from the requirements of their production (Moore 2012) or their use. It is arguable that it has not been demonstrated that nonhumans even comprehend indexes they created and we do not know when hominins began to comprehend them.

Most early artifacts were constrained in their forms by the utilitarian mechanics of production or use. At some stage, people acquired the skill to vary the form of the artifacts to their perceptions of how an artifact should be – Mellars (1989) referred to this as "imposed form" without ever defining what that meant or how it could be recognized – such that by freeing the artifact from its utilitarian constraints, the form became arbitrary, but could be constrained by the convention associated with those perceptions. Thus, one possible definition is that "the form of an artefact can be seen to be imposed if their shape did not depend on any aspect of the mechanics of production or use, if the modified edge was not that used, and if the forms were standardized within a very narrow range of possible forms" (modified from Davidson 2002). Such artifacts could be seen to fit within the broad definition of symbols, given both arbitrariness and convention. But this definition is not straightforward since some archaeologists would see a deliberate intention to produce "handaxes" and so include early bifacially flaked cores from the Acheulean, and others would not (Davidson 2002).

One productive way to think of the cognitive complexity of artifact production is to document fully the steps required to produce them (Haidle

2010; Lombard and Haidle 2012). Moore (2010) stressed the importance of hierarchical sequences of knapping, while Davidson (2010c) emphasized that cognitive complexity could be identified from episodes of knapping that were unrelated to the target artifacts on the core. This displacement is reminiscent of the distraction tasks that are central to experiments in establishing Working Memory capacity (Conway et al. 2005). The event that is both the most indisputable example of modern human behavior and demonstrates this property of displacement unequivocally is the seafaring habits that must have underlain the several voyages between islands that took modern people to Australia around 50 thousand years ago (Davidson 2012b). It seems likely that further analyses along these lines will be productive in understanding cognitive evolution.

One example which seems to demonstrate early cognitive sophistication is the claim for heat treatment of stone prior to knapping at the site of Pinnacle Point in South Africa (Brown et al. 2009). If the dating is reliable, this example dates back to 162 ka, much earlier than anywhere else in the world.

Future Directions

Phylogenetic Theory

One of the confounding factors in studying the evolution of cognition and the origins of language has been the apparent importance given to studies of the Neandertals, who were quite limited in their distribution (Europe and parts of western Asia), when many of the important evolutionary events took place in Africa and most of the modern people outside Africa are derived principally from movement out of Africa relatively shortly before Neandertals became extinct (Sankararaman et al. 2012). Models that do not acknowledge the branching nature of evolutionary trees are likely to be erroneous (Langbroek 2012). But, that said, there is a growing body of publications that claim increasingly complex behavior among Neandertals, such as hafting stone tools (Mazza et al. 2006), the use of feathers (Morin and Laroulandie 2012), the use of pigments (Roebroeks et al. 2012), and symbolic objects (Zilhão et al. 2010). All such claims need to be scrutinized carefully.

Similar claims, generally replicated at several sites, are also made for the most southern parts of Africa including the use of ochre in hafting (Wadley et al. 2009), use of pigments (Watts 2009), shells used in turning ochre into paint (Henshilwood et al. 2011), designs on ochre pieces (Mackay and Welz 2008), and shell beads (d'Errico et al. 2005), all earlier than the presence of modern humans in Europe, provided the chronology can be relied on. Given that the people who made these convincing markers of modernity were about as distant from Europe and Neandertals as it was possible to be, there is a puzzle that has not yet been solved to account for the apparent convergence on sometimes remarkably similar behaviors that seem to imply aspects of modern cognition. There are several possibilities: (1) evolution is actually directional and that hominins would all have evolved modern cognition given enough time; (2) some of the evidence in Europe has been over-interpreted, at least in part because of a desire by archaeologists to emulate findings outside Europe; (3) some of the evidence from one or other place was a response to contingencies that had little to do with modern cognition; (4) some of the evidence claimed to have been the product of Neandertal behavior was actually produced by modern humans; and (5) the hardware for cognitive modernity emerged before Neandertals separated from other hominins and took a long time to be expressed. All of these possibilities are very uncomfortable, but will need to be confronted in future research.

Genetics

In addition to the several suggestions made earlier, it is clear that the future will produce huge changes in our understanding of the past from the analysis of genetic sequences from modern people and from ancient DNA. But it cannot be stressed strongly enough that those inferences will only be as good as the theoretical framework in which they are conducted. Early hopes that the genes labelled FOXP2, or HAR1, or MCHP1, or ASPM might provide clear insight into the

evolution of modern cognition or language have proved problematic (see reviews in Davidson 2010a, b). Apparently random claims that modern cognition resulted from an unspecified genetic change (e.g., Klein 2000) will presumably be a thing of the past and will be replaced by evidence-based studies of the genetics that affect brains or behavior.

Other areas in which future studies of molecular biology will enhance understanding of the evolution of cognition will be in understanding developmental plasticity (Moczek et al. 2011), but such studies will only be relevant in the context of well-constructed arguments about the role of learning in cognition more generally and in particular about language acquisition.

Coimbra, Fernando Augusto

Fernando A. Coimbra
Geosciences Centre, Quaternary and Prehistory Group, University of Coimbra, Coimbra, Portugal
Polytechnic Institute of Tomar, Tomar, Portugal
Centro Português de Geo-história e Pré-História, Lisboa, Portugal

Basic Biographical Information

Fernando Augusto Coimbra is a Portuguese archaeologist, born in Lisbon in 1956. At the age of 10, he moved, with his parents and sister, to Oporto, where he finished high school and graduated in Archaeology in 1985. After that, he began to collaborate with older archaeologists in several fieldwork projects and to participate intensively in international conferences. He started to direct his own archaeological excavations in 1991 in an Iron Age Hillfort in the north of Portugal. His interest regarding rock art started in 1994, after discovering new engravings, very eroded, on a previously published rock in the 1950s. In 1997 he was invited to work at the Museum and Archaeological Site of Conimbriga, and 1 year later he became a collaborator of Dipartimento Valcamonica of Centro Camuno di Studi Preistorici (Italy). In 2003 he was invited to be a member of the Scientific Committee of the Hellenic Rock Art Centre (Philippi, Greece). He completed his Ph.D. in Prehistory and Archaeology, with the highest classification and an extraordinary prize, at the University of Salamanca, in Spain (2007). After this, he was invited to teach in the Master in Prehistoric Archaeology and Rock Art, organized by the Polytechnic Institute of Tomar, and to be an integrated researcher of the Quaternary and Prehistory Group of the Geosciences Centre of the University of Coimbra. Since then he has supervised several Ph.D. and Master theses, being also a member of the jury of several of those dissertations. In 2010 he completed postdoctoral research about Bronze Age

Coimbra, Fernando Augusto, Fig. 1 Fernando Coimbra lecturing about rock art

and Iron Age Rock Art in the Portuguese Middle Tagus Basin. In 2011 he started to collaborate with Portuguese Centre of Geohistory and Prehistory, being now one of the two vice-presidents. From 1991 to the present, he has given frequent lectures, by invitation, about archaeology and rock art, in countries such as Portugal, Spain, France, Italy, and Greece (Fig. 1). Besides Portuguese, he speaks English, French, Italian, and Spanish. He loves music, traveling (Fig. 2), and going to the beach. Scientific interests are cognitive archaeology, rock art, Metal Ages, sound archaeology, and archaeoastronomy.

Major Accomplishments

Fernando Coimbra has been a member of several international projects regarding archaeology and rock art. He directed several fieldworks in rock art in Portugal, namely, within the project *RUPTEJO – Rock Art of the Tagus Basin* (Fig. 3), and co-directed similar projects in Greece (2005, 2006, and 2010) and in Liguria, Italy (2008). He coordinated sessions at the UISPP/

Coimbra, Fernando Augusto, Fig. 2 Fernando Coimbra at Maison Carrée (Nimes, France)

IUPPS Conferences in Lisbon (2006),

Coimbra, Fernando Augusto, Fig. 3 F. Coimbra tracing post-Paleolithic incised rock art

Florianopolis (2011), and Burgos (2014), and he is organizing two sessions for Paris (2018). He is the author and scientific editor of several books, some of them in collaboration with archaeologists such as Umberto Sansoni, Rafaella Poggiani-Keller, and Davide Delfino, among others (Coimbra and Delfino 2016; Coimbra and Sansoni 2016), and published more than 80 scientific articles, in English, Portuguese, and Italian, collaborating with a large number of different colleagues (Coimbra 2015a, b).

In 2013 he was the director of the Organizing Committee of the International Conference – *The Horse and the Bull in prehistory and in History* (Coimbra 2016a). Since February of 2014, he become interested in archaeoacoustics (sound archaeology) (Coimbra 2016b, c), participating in the *The Hal Saflieni Hypogeum Acoustic Project* (Malta) (Debertolis et al. 2015). In 2015 he wrote the prologue of the proceedings of Archaeoacoustics II (Istanbul), and he's a member of the Organizing Committee and of the Scientific Committee of the Conference Archaeoacoustics III (Tomar, Portugal, 2017).

He was the scientific coordinator of the itinerant exhibition about rock art – *Arte Rupestre do Pinhal Interior* – and of the exhibition at the Museum of Conimbriga (*The Swastika, Since Its Origins till the Roman Period* (1999)). In 2010, after formal invitation, he edited the Portuguese version of the Rock Art Glossary, published by the International Federation of Rock Art Organizations. In 2012 he participated in the exhibition *Prehistoric and Contemporary Interventions in the Landscape. Rock Art & Land Art*, organized in the Folklife and Ethnological Museum of Macedonia, Thrace (Thessaloniki, Greece), presenting, in collaboration with Ivo Oosterbeek, a video entitled *Protohistoric Horse Riders beyond the Pillars of Heracles.* He is a referee of several scientific journals, such as *ARNAVA* (New Delhi) and *British Journal of Interdisciplinary Studies* (UK), among others.

Presently, F. Coimbra is coordinating a team of archaeologists regarding the archaeological inventory of the municipality of Chamusca, Santarém, Portugal.

Colani, Madeleine

Lia Genovese
Independent Scholar, Bangkok, Thailand

Basic Biographical Information

Madeleine Colani (Fig. 1) was a geologist and an archaeologist born in 1866 (Encyclopædia Universalis) in Alsace (Northeast France) to

Colani, Madeleine, Fig. 1 Madeleine Colani. Photographie EFEO, Fonds Cambodge, Ref. 20001

Timothée Colani, a French Protestant pastor, and Josephe Marie Gauthey, a Spanish shopkeeper's daughter. The Franco-Prussian War (August 1870) led to the annexation of Alsace when Strasbourg raised the white flag (September 1870). To preserve their French identity, the Colanis relocated first to Royan (Fig. 2), on the French Atlantic coast, and then to Paris, where Madeleine qualified as a primary school teacher (1884).

Timothée's death in 1888 left behind a housewife widow, as well as 22-year-old Madeleine and three minors aged 11, 13, and 17. Exhibiting the industrious streak often associated with a Calvinist upbringing, Madeleine assumed the breadwinner's mantle, supplementing her teacher's salary with private tuition classes in drawing.

Colani was accepted for a position in French Indochina (1898), where she taught at primary schools from 1899, while pursuing distance learning for a geology degree through the University of Paris (Colani 1914). The Hanoi-based Geological Survey of Indochina (GSI) invited her to join their ranks, where she was the only female geologist (1914–1928). Her fieldwork to Indochina and Yunnan (1916–1919) formed the basis for a PhD at the University of Paris, with a thesis on fusulinids (Colani 1920) examined by Gaston Bonnier, Professor of Botanics at the Sorbonne University.

She critiqued some of the work by the GSI geologist Jacques Deprat (Colani 1924), suspected of scientific fraud (Genovese 2011). The discovery of a large deposit of Neolithic skulls and stone artifacts at Lang Cuom, in Vietnam's Bac Son mountains (Mansuy and Colani 1925), enhanced her standing as a prehistorian.

Reaching the statutory retirement age of 60, Colani sought to remain in active service (Genovese 2015) but was forced to retire (1926). She successfully negotiated terms similar to other retired GSI male geologists, namely, paid contract work (1926–1928). In 1929, the Hanoi-based École Française d'Extrême-Orient (EFEO) invited her to join their ranks (EFEO biographies) as a corresponding member (Genovese 2018). She continued with prehistoric surveys (1929–1930), leading missions to the Plain of Jars of Laos (Fig. 3) in 1931–1933 (Genovese 2016) and to the burial urns of Sa Huynh in Central Vietnam (Colani 1937).

Her participation at the first Far-Eastern Prehistory Association (FEPA) conference in Hanoi (1932) and the publication of her monograph on the Laotian megaliths (Colani 1935) enhanced her international reputation. Leading further missions to Vietnam (1935–1936), she discovered large deposits of polished stone and axes. She represented the EFEO at prehistorians' conferences in Manila (1935) and Singapore (1938).

In Vietnam, she surveyed more rockshelters (1937) and explored prehistoric caves in Halong Bay (1938) together with Johan G. Andersson (Fig. 4), founder of Stockholm's Museum of Far Eastern Antiquities, followed by an expedition to the Bronze Age site of Samrong Sen in Cambodia (1938).

Colani made her final field trip to the stone jars of Laos (1940) and continued to publish and lecture until her death on 2 June 1943 in Hanoi.

Modèle n° 2.

TRAITÉS DU 10 MAI ET DU 11 DÉCEMBRE 1871.

OPTION POUR LA NATIONALITÉ FRANÇAISE.

(1) Dates du jour et du mois. — Le (1) Vingt-deux Juillet 1872,

(2) Noms de la commune, de l'arrondissement et du département. — par-devant nous, maire de la commune de (2) Royan, arrondissement de Marennes, département de la Charente-Inférieure,

(3) Nom et prénoms du déclarant. — est comparu(e) (3) Colani Madeleine

(4) Indication du lieu de naissance. — née à (4) Strasbourg (Bas-Rhin)

(5) Date de la naissance ou au moins indication de l'âge du déclarant. — le (5) 13 août 1844

(6) Ajouter pour les mineurs, quand leur déclaration sera faite *séparément* : « Assisté de son père ou de son tuteur. » — (6) assistée de son père

lequel, conformément aux articles 2 du Traité du 10 mai et 1er de la Convention additionnelle du 11 décembre 1871, a déclaré opter pour la nationalité française, qu'il entend conserver.

(7) Ajouter, quand la déclaration sera faite collectivement par le père et ses enfants mineurs : « Ladite déclaration faite tant au nom « personnel du sieur « que comme représentant légal de ses « enfants mineurs. »

Nota. Indiquer les noms, lieux et dates de la naissance de chacun des enfants. — (7)

(8) Ou attestation par le maire qu'il ne sait pas signer.

Signature du Déclarant (8). — Madeleine Colani

signature du père : T. Colani

Signature du Maire, — dix-neuf mots rayés nuls, trois rejetés. — T. Garnier

Mairie de Royan (Charente-Inférieure)

Colani, Madeleine, Fig. 4 March 1938. Madeleine Colani, with Nguyen Ngoc Tran and Johan G. Andersson, on fieldwork in Dong Mau, an excavation site in the Bay of Tonkin. (Copyright: École Française d'Extrême-Orient)

Major Accomplishments

Colani coined the term Hoabinhian (Colani 1929) for stone artifacts (Hoabinhien, *Industrie Paléolithique*) dated to 10,000–5,000 BCE. She surveyed over 40 caves in Laos and Vietnam (Fig. 5), to inform the world about Indochina's prehistory.

Until the late 1920s, the lion's share of the EFEO's budget was devoted to the study of Asia's languages, religions, and architecture, particularly Cambodia's temples. Colani's field experience was critical when the EFEO widened its research remit with the inclusion of Laos and Indochinese prehistory.

At the Plain of Jars, Colani collected a rich haul of objects, including gold and bronze. Her monograph provides an inventory of all artifacts (Fig. 6), allowing for analysis while they remain

Colani, Madeleine, Fig. 5 Lang Vanh Cave in Hoa Binh, Vietnam, surveyed by Colani in 1929. (Photo: Lia Genovese)

in storage at the National Museum of Vietnamese History in Hanoi, beyond the reach of researchers.

To develop a regional perspective, Colani forged links with scholars in South and Southeast Asia. When research was being curtailed by budgetary constraints, she secured funding from Johan G. Andersson, who relinquished to her his excavation budget (1938) to advance the study of Indochina's prehistory.

A century ago, Colani surveyed remote corners of Indochina, frequently sleeping on a hastily made bed of leaves, surviving on daily rations of sticky rice and bananas. She battled malaria and dengue fever and was undefeated by superstition and the occult, which occasionally instigated desertion among her porters.

Colani is the only archaeologist to have documented all three megalithic expressions in Laos: stone jars, menhirs, and funerary stones. With close to 100 titles to her name, she was one of the most prolific scientific writers of her generation. In addition to French and German, she was fluent in English and reviewed books in this language (Colani 1930). Her descriptions are the only reference for the stone artifacts which have since disappeared from the Plain of Jars, as a result of urbanization, exposure to the elements, or human neglect.

She was a lifetime member of the French Prehistoric Society and received France's order of merit, the Légion d'Honneur (1937), together with a substantial grant from the French National Centre for Scientific Research (CNRS). She is listed in the International Directory of Anthropologists (Research Council of the USA, 1938) and in the French National Archives (Fontainebleau, dossier 19800035/742/84252).

Six months after Colani's death, her role in shaping our knowledge of Indochina's prehistory was commemorated by the EFEO with a conference in Hanoi on 6 December 1943 (Lévy 1944).

Cold War

Wayne D. Cocroft
Historic England, Cambridge, UK

Introduction

The study of the physical legacies of the Cold War is self-evidently a new topic. It is also a specialized area within the broader field of contemporary archaeology. In common with the early development of other period studies, investigations of its military monuments have dominated over the last two decades. As memories fade of the East–West standoff between the end of the Second World War and 1990, the archaeological study of its physical traces is able to bring new perspectives on the era. An extraordinary amount of documentation survives for the period, and more official material is likely to be released. Conversely, there is a steady loss of the physical traces of the Cold War and the generations with firsthand knowledge of the confrontation. In contrast to archaeological studies of the two world wars, which are generally encapsulated under the term "conflict archaeology," in the West, research into the Cold War is the investigation of the might have been. It was the world of the spy novel and films, such as *Dr. Strangelove* and *On the Beach*, and the BBC TV drama *The War Game* that tried to imagine the unimaginable. Elsewhere, bloody proxy wars were all too real. The Cold War was also more than a military standoff, and to understand this multidimensional theme, archaeological methods will rarely be used alone.

Definition

The Cold War may be defined as the standoff between the opposed economic systems of capitalism and communism, and their principal protagonists the United States and the Soviet Union. Chronologically, the seeds of the confrontation were sown in revolutionary Russia in the early twentieth century and came to a head in the redrawn European boundaries that followed the

Second World War. Similarly, there was no neat end to this confrontation that started with economic strains in Eastern Europe in the 1980s, exacerbated by increased arms spending by the West, a mixed message that resulted in the opening of the Berlin Wall in November 1989, and finally the breakup of the Soviet Union in December 1991. In its wake followed the bloody civil war in former Yugoslavia and massive political, social, and economic realignments.

The political and economic divisions of the Cold War were accompanied by a massive arms race. The militarism this stand-off engendered quickly spread into the civilian world and was reflected in state-funded science and technology programs, utopian visions that were played out in public housing schemes, and many other aspects of culture, including architecture, art, film, and literature. Although, "Cold War" may be a useful shorthand term to describe the period of East–West confrontation between about 1947 and 1990, the period may be defined by other criteria. In Eastern Europe, the material culture of this period might be more readily defined as "socialist" or "communist" (Buchli 1999). Elsewhere in Africa, South America, and parts of Asia, the effects of the Cold War took far longer to manifest themselves. In the West, and particularly among cultural commentators and architectural historians, the period is more usually referred to as "post-war."

Historical Background

The years following the end of the Second World War were characterized by many privations on either side of the Iron Curtain. In Britain, rationing continued, and new domestic goods and clothing were produced to "utility" standards, designed to use the minimum amount of materials and labor in their production. In post-war Germany, people were largely reliant on salvaged goods, swords were beaten into plowshares as helmets, and gas mask canisters were fashioned into enameled domestic utensils and containers.

In considering the material culture of the period, the picture we might reconstruct from purely archaeological sources might be seen to lag behind actual historical events. In the late 1940s, both sides were armed effectively with wartime equipment, but as new national identities and allegiances strengthened, the arms and uniforms of military and paramilitary forces often began to reflect those of the dominant superpower. Similarly, there were huge numbers of surplus military and other state facilities, and there was little need for new military building projects. Slowly either side began to design the equipment and facilities they required to compete in an increasingly technological standoff, a confrontation that was dominated by newly emerging technologies, the atomic bomb, jet engines, long-range missiles, and radar, all supported by increasingly sophisticated electronics. The technical artifacts of this era often betray complex genealogies, for example, rocket and missile projects in East and West often incorporated captured German technology with existing indigenous programs. Original objects, which may be recovered from archaeological contexts, can provide important information on variations in build qualities, differences in metallurgical competence, and contrasting national engineering styles.

In the United Kingdom, it was not until after the outbreak of the Korean War in 1950 that distinctive military facilities built to meet changed defense needs can be recognized. Nor was it not until the end of the decade that the country was fully equipped to meet the perceived threats of the Cold War, with airfields for jet fights and bombers, atomic bomb stores, new radar systems, and surface to air missile sites.

Elsewhere, different construction chronologies are found. In former East Germany, a legacy of heavily constructed wartime bunkers was available for adaptation by Soviet and later East German forces. Across Europe, in the aftermath of the Second World War, the physical expression of the agreed political demarcation line between western and eastern areas of influence was often no more than a barbed wire fence. Initially, its wooden watchtowers appeared more medieval than a product of the atomic age. As the political divide hardened, differences between the two blocs became manifest in messages displayed on billboards among the ruined cities.

Key Issues/Current Debates

The study of the aspects of the Cold War by the use of archaeological methods is part of the wider debate about the contribution that archaeology can make to our understanding of the recent past. Although the Cold War is still well within living memory, detailed information on specific places may be lost, destroyed, or inaccessible. In Eastern Europe, the early excesses of many of the post-war communist governments are poorly documented. Excavations at the former Nazi concentration camp at Sachsenhausen, Berlin, have revealed its post-war victims and associated artifacts. In situations such as this, the scientific archaeological records may be the only evidence to document these events (Theune 2010). In many countries overrun by the Soviet Union, armed resistance to their occupation continued for up to a decade after the end of the Second World War. In Estonia, the Forest Brothers waged a guerrilla war from small, often wooden forest hideaways (Rasmussen 2010: 34–35). Investigations, such as these that reveal lost places and objects, can create a powerful stimulus for the local community to recount little known or suppressed episodes of national history.

In the West, dissent to the Cold War system was most evident in the peace movements and in particular their opposition to nuclear weapons. Archaeologically, their presence is almost invisible. The most common artifact is the pin badge decorated with a now internationally recognized peace symbol or other slogan, but without supporting oral testimony, it is an essentially context-less object. At a number of locations in Europe and North America, campaigners established semipermanent protest camps outside or close to military installations. Conditions in the camps were primitive, and accommodation was usually in commercial tents or as at Greenham Common, England, in "benders" created from a frame of withies covered in plastic sheeting. In form they resembled a type of crude temporary shelter constructed by hunter-gatherers. In the desert adjacent to the Nevada Test Site, North America, are the traces of a huge peace camp covering about 240 ha. Features within this area include cleared tent sites, hearths, gardens created by arrangements of stones around plants, and geoglyphs, symbols made from stones (Fig. 1). The techniques to document and interpret such sites are identical to the skills used by a prehistorian to understand the more distant past. It is possible to analyze the spatial relationships in the camp and also consider the symbolic relationships between these groups and the landscape. The investigation of such sites provides many opportunities for engagement with peace campaigners, artists, and, in the case of the Nevada peace camp, members of the Western Shoshone tribe (Beck et al. 2007: 297–320; Schofield 2009: 99–111).

Building Archaeology

Rapidly evolving military technology led to new types of military architecture and facilities, some were built to resist (as far as they were able) the effects of nuclear weapons and others to accommodate complex electronic equipment and weapon systems. From the perspective of the early twenty-first century, the military structures of the Cold War appear to represent the swan song for heavily built defensive installations. Their design and construction techniques are of interest to building historians. In some instances, excellent documentation will survive, including detailed drawings. More commonly, documentation is partial. In these instances, the sites and structures provide a valuable record of past activity. Where no original documentation survives, routine architectural recording skills may be needed to produce drawings. In the United States, the Historic American Engineering Record has produced exemplary record drawings of some Cold War facilities. An archaeological approach to such work brings with it questions about construction phases and subsequent modifications, building techniques, the character of functional areas, and about how buildings and sites operated as social spaces.

On closure, most military sites are usually stripped to remove valuable equipment and, if left unsecured, fall prey to metal thieves and

Cold War, Fig. 1 Nevada Test Site, the United States, outside the test site, extensive and fragile remains of the 1980s peace camp may be traced. They include traces of shelters constructed from withies secured by small piles of stones. (© W.D. Cocroft.)

Cold War, Fig. 2 The Teufelsberg, Field Station Berlin, a mural in the crew room of the security police unit. Later graffiti is a record of the many urban explorers who have visited the site since its abandonment. (© W.D. Cocroft.)

vandals. These may be seen as early taphonomic processes that lead to the creation of the archaeological remains we encounter. Within these now often empty spaces, official painted signs may offer clues to former uses. Also encountered are wall paintings and murals that can offer insights into the cultures of the different armed forces, units, and sections within them (Cocroft et al.

Cold War, Fig. 3 Bernauer Strasse, Berlin, part of the "Contemporary History Information Mile" to the left is a surviving section of the Berlin Wall and steel bars marking a lost section. To the right are steel posts that indicate the line of the hinterland wall and a typical East German lamppost. (© W.D. Cocroft.)

2006). On many Soviet bases, rooms were set aside for the political education of the forces, decorated with slogans and collages of images from newspapers and magazines. On western bases, large renditions of unit insignia are found, and in less frequented areas and semiprivate spaces, artwork may be used to personalize otherwise anonymous interiors (Fig. 2).

To date, where archaeological methods have been applied to the study of the physical remains of the Cold War, it has often been in the context of cultural resource management, in mitigation against loss, to assess monuments for legal protection or to provide the necessary knowledge base prior to public display (Cocroft and Thomas 2003). In 2002–2003, Klausmeier and Schmidt (2004) produced an archaeological record of one of the most iconic Cold War structures, the city section of the Berlin Wall (Fig. 3). Although, in most sections of the city, the wall facing onto the West was removed in the early 1990s, a considerable amount of the in-depth border defenses to the East were still present. This survey added considerably to the understanding of how this familiar structure had developed, incorporated existing urban features into the barrier, and the operation of the linear border landscape. As the border was approached from the rear, painted red and white marks on walls delineated the border area, and closer still a knee-high fence left a would-be escapee with no defense that they had inadvertently strayed into the restricted area. The routines of the watchers were equally proscribed, and painted stripes on lampposts marked the limits of the border troops' patrol paths (Fig. 4).

In many instances, archaeologists employed in cultural resource management will be required to investigate Cold War sites where there is imperfect documentation. The overall context of a site may be well understood from historical studies, but detailed site drawings and information about the modifications carried out at individual sites are often lacking. One characteristic of the Cold War was the stationing of foreign forces, usually of the dominant superpower, in allied or friendly countries. On withdrawal, documentation was often destroyed or lost or has become effectively inaccessible. In these instances, although the historical

Cold War, Fig. 4 Bernauer Strasse, Berlin, painted stripes on a numbered lamppost marked the patrol limit for a border guard unit. (© W.D. Cocroft.)

context of the site is known, the details of a site's development, use, and functions may be essentially ahistorical. In such a situation, archaeological methods of site and building analysis may be the only source of evidence. Beyond furthering academic knowledge, such studies may be a crucial part of wider environmental studies to determine past land use and present-day land quality. This lack of knowledge is particularly evident in many former Soviet bases in Eastern Europe that operated as closed entities and where contacting past personnel is fraught with difficulties.

The deployment of archaeological methods to investigate complex modern technology is an issue that goes beyond military weapon systems. Generally, many of the earlier systems that were based on electromechanical technology have left a more robust archaeological footprint than the later systems (Fig. 5), which through the increasing use of microprocessors have shrunk in size, become more mobile, and are based around anonymous black box technologies. As discussed, although this is an incredibly well-documented period, detailed information on individual facilities may be lost through changes in ownership, the withdrawal of foreign forces, or destruction of obsolete documentation. In doing so, people, places, and technology can become historically invisible. Through the investigation of their physical remains, they may be restored to the historical record.

Archaeology is also able to bring people into direct contact with the places directly associated with some of the most dramatic events of the Cold War. In 1962, the deployment of missiles by the Soviet Union in Cuba precipitated one of the most dangerous confrontations of the era. Aerial images of these sites are well known from contemporary USs' reconnaissance photographs. Recent fieldwork by a group of Swedish and Cuban archaeologists has located a number of the missile sites. The project also illustrates the communal value of such work: Local people were involved in the search for the sites and recalled their memories of the arrival of the Russians and the subsequent stripping of the sites for reusable materials (Burström et al. 2009, 2011). The work on Cuba also illustrates the global nature of the study of the archaeological remains of the Cold War. From Langelands Fort, Denmark, now preserved and open to the public, the passage of the ships carrying the missiles was monitored. In England, two of the Thor intermediate-range ballistic missile sites that were raised to alert during the October 1962 Missile Crisis are listed for their historic significance (Fig. 6). Archaeological studies may be able to answer questions about the fate of the contemporary US missile sites in Italy and Turkey that were quietly dismantled after the resolution of the crisis.

Many techniques of documentation and remote sensing employed by archaeologists have their origins in methods used by military forces to depict terrain or gather information on their opponents. Aerial photography that was developed in the First World War was quickly applied to discovery of archaeological sites and is an important source for the Cold War archaeologist. From the 1960s, imagery obtained from satellites was an increasingly important source for military intelligence. Since the end of the Cold War, growing

Cold War, Fig. 5 North Coates, Lincolnshire, England, the horizontal stratigraphy of this surface to air Bloodhound missile pad shows a cable channel for a later system that cuts the line of the original 1950s' cable conduit. (© W.D. Cocroft.)

Cold War, Fig. 6 North Luffenham, Rutland, England, mounting bolts for a Thor missile launch mounting. American-supplied Thor intermediate-range ballistic missiles were operated by personnel from the British Royal Air Force and were raised to alert status throughout the Cuban Missile Crisis in October 1962. (© W.D. Cocroft.)

amounts of satellite photography have been made publicly available. It is an important source of information for archaeologists, especially for more remote areas of the world. Using techniques analogous to the military analyst, it has been used to study the development of otherwise inaccessible Soviet missile sites (Fowler 2008, 2010). The Cold War's technological rivalries have also created an extraterrestrial legacy. Circling the earth are redundant spy satellites and their components and on the moon traces of man's first visits. These sites have been remotely mapped and measures to ensure their survival promoted (Darrin and O'Leary 2009).

Just as artifacts reveal information about the past to archaeologists, they too are of interest to the military intelligence officer. Equipment of the opposing forces was eagerly sought after on the proxy battlefields of the Cold War. More akin to techniques of archaeology, western military missions in East Germany collected discarded documents and objects from Soviet rubbish tips (Geraghty 1997: 208–11). Some were even subject to scientific analysis to reveal their composition. It has taken nearly a century for the material culture of the First World War to be studied. Dumps such as these, and ones associated with Cold War's battlefields, may in the future yield valuable information about various camp economies and the everyday life of the Cold War warrior. Military intelligence and archaeology also bear similarities in their limitations: Both are effective at locating and describing activities, but less successful in understanding motivations.

Another characteristic of twentieth-century warfare was its insatiable appetite for land. The application of industrial methods to armament production produced devastation on previously unknown scale. The military required large areas for training, testing new weapons, accommodation, munitions production sites, airfields, and border regions that became increasingly militarized and inaccessible to most civilians. Many of the areas already under military control continued in occupation during the Cold War. Airfields were remodeled to accept new jet aircraft and commonly cover a few hundred hectares. Weapon testing has created some of the most distinctive landscapes. At the Nevada Test Site, North America, its pockmarked surface attests to the awesome power of nuclear weapons, and many of the associated facilities have been documented by the Desert Research Institute, Las Vegas. In Albania, the communist regime headed by Enver Hoxha broke with its communist neighbors. The ensuing national paranoia about attack from the West and East is reflected by hundreds of thousand mushroom-shaped bunkers, or pillboxes, dotted across the country, roughly equating to one for every four or five citizens (Galaty et al. 1999: 201). Since the 1990s, they have been appropriated for storage and beach bars and modeled as tourist trinkets that have become a national icon.

International Perspectives

The Cold War was a global phenomenon. Archaeologically, the political and military allegiance and patronage was marked by the distribution of material goods from the two trading blocks. Allegiances were most visible in the supply of military equipment and the design of associated facilities. To date, the study of Cold War installations has been primarily motivated by cultural resource management studies. Over the last 20 years, these have vastly increased our understanding of places that a generation earlier were off-limits. Many Cold War era facilities are still in military hands and are at present unavailable for direct study. In the states of Eastern Europe that were formerly under Soviet dominance, it is often sites that commemorate political repression that have been studied, given official recognition and opened to the public. Their military bases may remain in use, or the Soviet bases may represent a past, which people wish to forget and sweep away.

As each side consolidated their grip on Europe, globally they sought to extend their influence through the use of proxies. In its most cynical form, it appeared to be based on the policy that my enemy's enemy is my friend. The allegiance of these friendly states became readily recognizable as they were supplied with arms of western and eastern origin, although occasionally they would provide captured arms to disguise their true origin.

As the post-war divide in Europe hardened, in the Pacific region that had already witnessed the operational use of two atomic bombs, the United States prepared to test the effect of atomic weapons on an obsolete fleet of American vessels, a German battle cruiser, and captured Japanese battleships. The July 1946 Bikini Atoll tests in part represented the symbolic end of the enemy's naval power, but they were also a demonstration of the USs' supreme military might. The remains of these tests have been subject to archaeological analysis, including the underwater investigation of ships deliberately sunk as part of the experiments (Delgado 1996, 2009). These tests marked the beginning of numerous tests across the Pacific Micronesian islands by the United States, Great Britain, and France. They have left a physical legacy of damaged landscapes, in places the infrastructure built for the trials, but more disturbingly displaced communities, radioactive deposits, and uncertain health risks (Smith 2007: 51–72).

The needs of Cold War scientists and military forces also resulted in the creation of new places. Research establishments were often built in places now valued for their natural beauty or remoteness. In sparsely populated areas, new settlements were created. Some facilities were utilitarian bases for military personnel, while new settlements for research communities often followed contemporary urban planning considerations. At Woomera, Australia, a new town was created with chalet-style bungalows and large communal facilities to serve the new long-range weapon project (Garnaut and Freestone 2007). In the West, the need to attract high-grade research staff often resulted in high-quality settlements. Behind the Iron Curtain settlements, serving large military facilities and research establishments became closed towns, but were nevertheless often provided with lavish cultural facilities (Fig. 7).

Future Directions

In most countries, the study of the physical legacy of the Cold War is still in its infancy. For the development of cultural resource management policies toward this heritage, inventories have yet to be compiled. Ironically, such information may survive within the classified archives of the Cold War targeteers who planned to destroy the places people may now seek to study and preserve.

Since the end of the Cold War, abandoned military sites have undergone a variety of taphonomic processes that are creating the archaeological record of the Cold War. In its most extreme form, this might be demolition to comply with

Cold War, Fig. 7 Falkenhagen, Brandenburg, Germany, raised rendition of the Kremlin in the cultural center of a Soviet military establishment. (© W.D. Cocroft.)

treaty obligations or to free land for new uses. Where sites do survive, on closure, they have been subject to official stripping out, looting of saleable materials, and vandalism that has hastened their decay. Nature has also quickly weathered their exteriors and reclaimed deserted buildings. Some have had an afterlife inhabited by squatters or occupied by businesses that often operate on the margins of society, such as vehicle breaking and recycling centers.

Over the next decades, oral testimony has great potential to provide multiple narratives of places and artifacts, from people who worked within the system. Among civil communities who lived close to military, their experiences will differ greatly; some valued the direct and indirect employment opportunities brought to an area, while elsewhere there was resentment of the noise, social tensions, and access restrictions brought by a military presence. A feature of the Cold War was the stationing of foreign military personnel in the countries of their allies. The division of cultures represented by the military installation and foreign personnel, with the local, is likely to have left particularly strong memories.

Within this area a particular urgency is to investigate places, events, and artifacts associated with the early phases of the Cold War. With the passage of time, communities, military and civil, will disperse, and it is increasingly difficult to find people associated with a particular place or event. Of particular significance are social aspects of the Cold War that may be absent from official histories and documentation. In Eastern Europe, this may include stories of resistance to communist rule. Across Europe, the opening years of the Cold War were also characterized by mass migration and the gradual restoration of civilian domestic life, albeit against the developing background of increasing East–West tensions. Investigations of immediate post-war adaptations to army camps, and perhaps associated rubbish tips, could reveal more of this history: as might the study of prison camps that housed many millions of captured German soldiers.

Each country has a unique assemblage of sites and artifacts reflecting its experience of the Cold War. The availability of primary documentation will also vary between countries and individual sites and in many instances may not answer the questions we wish to ask. Different national, regional, and personal experiences and local heritage cultures will also frame the questions that might be asked of this material. In the West, to date, these have mainly been concerned with the physical legacy of former defense sites. Elsewhere, questions concerning occupation, resistance, and liberation are at the fore. In other parts of the world, the study of the contemporary past using archaeological methods is either in its infancy or at present little accepted. In all countries, researchers will also find restricted access to sites and documentation relating to the Cold War, though, as discussed, new technology is able to remove some of these barriers. The complexity and multidimensional nature of the Cold War will require a multidisciplinary approach, archaeological methods will rarely be used alone, and most projects will combine elements of historical geography, building analysis, documentary research, and oral testimony.

Collaborative for Cultural Heritage Management and Policy (CHAMP)

Helaine Silverman
Department of Anthropology, University of Illinois at Urbana-Champaign, Urbana, IL, USA

Basic Information

CHAMP (Collaborative for Cultural Heritage Management and Policy) is a strategic research center at the University of Illinois at Urbana–Champaign that is dedicated to the critical study of cultural heritage and museum practices on a worldwide scale in the context of globalization.

CHAMP's goals are to:

- Promote faculty research and dialogue across disciplines
- Train students in heritage and museum theory and practice
- Advocate sustainable and ethical cultural policies that are sensitive to competing stakeholder claims at heritage sites and museums
- Offer public dissemination of ideas generated through CHAMP's activities

CHAMP's interests are international and comparative in scope, especially in terms of the intersections among often conflicting local, regional, national, and international agendas in which cultural heritage issues intervene. CHAMP's integrative approach links critical inquiry to

opportunities for problem-solving in the field. CHAMP's premise is that there must be engagement between theorists and heritage managers so as to achieve state-of-the-art practice.

CHAMP interrogates museums as heritage sites and as dynamic engines for economic development in their regions. Museums take many forms – from object collections contained within buildings to open-air historic sites to world's fairs and theme parks to reenactments and other kinds of performances. All of these are venues for the articulation of cultural identity – sites for cultural production, formation of social consciousness, and construction of history.

CHAMP recognizes "landscape" as the most visible locus where displays and contestations of identity, ownership, and ideology are inscribed and mediation takes place. This built environment necessarily includes its inhabitants. While heritage is an important component in the articulation of identity, unfortunately it is also a basis for conflict of various sorts. Out of this complicated situation arises an important opportunity for study and mitigation.

As countries develop, their cultural heritage sites often become prominent in national economic agendas. Under pressure from tourism, their integrity and sustainability may be endangered as are their associated living populations. CHAMP is necessarily interested in tourism as this is a major factor in cultural heritage promotion, cultural change, and economic development around the world – at sites (archaeological, historic, cultural), at museums, and among "traditional peoples" when these are scripted and commercialized as major travel destinations. CHAMP recognizes the manifold problems and challenges of multiple constituencies voicing heritage claims and investigates the kinds of policies that can play a positive role in social, political, and economic terms.

Major Impact

More than two dozen University of Illinois faculty from multiple academic departments housed in various colleges participate in CHAMP. They offer a broad range of courses and conduct projects around the world. Several CHAMP scholar-practitioners consult for governmental, intergovernmental, and nongovernmental agencies at various levels on issues such as historic preservation, sustainable tourism, economic development, and human rights. Graduate students pursue interdisciplinary minors in Heritage Studies and in Museum Studies en route toward their doctorates in particular academic fields. Through coursework and practicums, CHAMP faculty are training a new generation of heritage scholars, heritage managers, and museum professionals capable of dealing with complex realities and of articulating sound progressive policies to local and national governments and other agencies.

CHAMP's most important impact has been through its conferences and, especially, the edited volumes that have resulted from these. Thus far the conferences have yielded five edited volumes: *Cultural Heritage and Human Rights* (2007), *Intangible Heritage Embodied* (2009), *Contested Cultural Heritage* (2011), *On Location: Heritage Sites and Cities* (2012), and *Cultural Heritage Politics in China* (in press) – all with Springer Publishers. The volumes have attracted wide attention and stimulated productive dialogue.

The Collapse of Complex Societies

Rebecca Storey[1] and Glenn R. Storey[2]
[1]Department of Comparative Cultural Studies, University of Houston, Houston, TX, USA
[2]Departments of Classics and Anthropology, University of Iowa, Iowa City, IA, USA

State of Knowledge

For at least the last few decades, the question of the "collapse of civilizations" has been the focus of academic study and the subject of popularizing books (e.g., Tainter 1988; Diamond 2005). Books continue to appear about this, looking to educate interested readers about what it means for a society to collapse and what is involved (e.g., Johnson 2017; Middleton 2017). Interest in this subject, at least in the complex societies of what is commonly called Western Civilization, appears to be insatiable. Although widely used only recently, terms such as "sustainability," "resilience," and "transition" have also become part of this study, providing the counter terms to collapse. Archaeologists are part of this focus, inasmuch as the discipline's greater time depth across a wider range of societies allows systematic exploration of the past, although usually it cannot provide fine temporal control to explore all problems in great detail. So, scholars are looking for societal examples of the kinds of social transformations indicated by the above terms. Above all, they seek some guidance as to why these changes occur, and archaeology can provide evidence of these.

Three important texts on collapse for archaeologists in the last 30 years are Joseph Tainter's (1988) *The Collapse of Complex Societies*, the edited volume of Norman Yoffee and George L. Cowgill (1988) *The Collapse of Ancient States and Civilizations*, and Jared Diamond's (2005) *Collapse: How Societies Choose to Fail or Succeed*. Of these three, Tainter's volume had the most influence on the profession of archaeologists, while Diamond's has had the most influence in the popular realm (although academics use the text often in courses). Yoffee and Cowgill's edited volume is interesting in that it highlighted how Roman scholars (as exemplified by the participating Romanist, G. W. Bowersock) were turning away from the belief that the Roman Empire had collapsed. Now, some investigators of regions represented in the volume also appear to recently reject collapse as not a useful concept. In terms of explanatory power, Tainter's setting out of the problem of declining marginal returns in the evolution of complexity probably has had the most impact. Diamond highlighted the challenges facing the world today by featuring some notable examples of societal collapses of the past, in a very much didactic fashion. That resonated with a large audience. The weaknesses in Diamond's contribution will be touched on subsequently.

There are two basic approaches to the question of the collapse of complex cultures. The first is the traditional, older approach that regards the collapse of cultures as something that took place reasonably frequently in the ancient world. That approach regarded collapse as an ending of the *floruit* of an ancient culture. The newer, more recent approach to collapse, in its most extreme form, denies that collapse really takes place at all. In its less extreme form, that approach acknowledges that some degree of collapse takes place but maintains that the most important feature of the process is that there is cultural resilience and that the culture reconstitutes or regenerates itself into a different, somewhat related, form. So, rather than being focused on an ending, the newer approach is focused on beginnings – or the continuation of the culture in an altered form.

What is common to both approaches is the recognition that the culture in question has ceased to function in the same manner as during its *floruit*. And, although the newer approach does not emphasize it so much, both approaches also recognize that a prime feature of the entire process is a loss of population, demographic decrease on a large scale. Even in its most extreme form, the new approach acknowledges that essential feature of severe demographic decline while claiming that cultural collapse is a concept that should be abandoned because, with the admission of demographic decline, collapse is analogically likened

to biological extinction. But, as almost all students of past cultures know, virtually no known complex society has ever gone completely extinct – that is, every member of a culture died off. Although the Teotihuacanos of the famous Precolumbian city no longer form a coherent society, those people did not all die off at once but contributed both genetically and culturally to the continuance of Mexican cultures. Collapse researchers recognize that and generally acknowledge survivors, so an extreme interpretation of the concept of cultural collapse as extinction, is not warranted.

Regarding the traditional approach, the reason why the interest in collapse is so common in complex societies is explained by Tainter (2016). People in complex societies have a natural bias towards complexity because they have internalized a "progressivist view of human evolution" (Tainter 2016: 31). We humans believe that our complex society is the highest achievement of humans as an example of civilization, and it is the best, we think, because it represents the height of inventiveness and provides such a wealth of possibilities in life. It follows then that to lose this complexity must be a bad thing. When a culture collapses and loses this complexity, it is a form of failure. As will be discussed, there have been cases of human culture that fit this description of loss of complexity and richness of life. Tainter laments, however, that even professionals (ourselves included) are guilty of furthering this biased view by use of progressivist terminology, repeating terms such as *rise, decline, dark ages, florescence, classic, and postclassic* (Tainter 2016).

The newer approach has declared that commonly used progressivist terms should be thrown out, advocating the use of preferred terms such as "change," "transition," "transformation" or "resilience." That is accompanied by the assertion that "decline," "fall," or "collapse" are biased and full of preconception, and so no longer acceptable. As much as we wish there were alternatives to the terms used, there are none, so each investigator must define clearly what he or she means by their use of the terms (Tainter 2016: 33).

The study of collapse, however, is contentious precisely because there is so much to disagree about. For one, change in human societies is ubiquitous and as environmental historian J.R. McNeill has written, "only with the most flexible of definitions could one say that any of the cultures in existence 1,500 years ago exist today" (2010: 362). So do all societies eventually collapse? We shall take up that theme again at the close of this article. Most researchers have very definite ideas of what kinds of societies collapse or are prone to it. Also, most researchers, as will be detailed below, recognize that the process is not simple, or attributable to one cause. In fact, a new book on collapse indicates that collapse could be studied at various levels and types of human collectives from individual communities to empires, as well as finding no great overarching grand theory to explain all possible cases (Middleton 2017). Another recent contribution (Johnston 2017) agrees that any explanation for societal collapse must be multi-causal maintaining that "social hubris" of the society's leaders was a most important factor in most cases of collapse. We have recently argued (Storey and Storey 2017) that collapse is multi-causal but generally slow.

Definitions

Before discussing collapse and resilience, sustainability, and other issues, these terms should be defined, although there will be disagreement, because so much is subjective, without widely accepted measures to back the definitions. Various definitions have been given for collapse, but most researchers agree that the term is best used in relation to complex societies and civilizations. Archaeologists quote Renfrew's definition (1984: 367–369) which is a sudden decline in sociopolitical complexity marked by disappearance of central administrative organization. Furthermore, traditional elites disappear, the centralized economy fails, and settlement and population decline (quoted in Faulseit 2016 for example). Those aspects of collapse are marked archaeologically by such evidence as the

abandonment of palaces and large public works. Many large nucleated settlements shifted to dispersed smaller settlements with lower population density and less internal and long-distance trade, among other indicators.

Also influential is Tainter's definition (1988: 4–5) which defines collapse as a loss of complexity in the sociopolitical sphere – a process of simplification. Societies use complexity, more integrated parts, and hierarchical organization to solve problems and adapt. Adding complexity, however, eventually yields declining marginal returns and ends up being too costly to maintain. Collapse for Tainter can be seen then as adaptive (Middleton 2017). Diamond's definition of collapse (2005: 4) has drastic loss of population and sociopolitical complexity over a significant geographical area for a significant period of time. Schwartz's definition is notable (2006: 5–6), because he provided it in a context of focus on resilience as exemplified in regeneration: "Regeneration presupposes collapse. In the archaeological literature, collapse usually entails some or all of the following: the fragmentation of states into smaller political entities; the partial abandonment or complete desertion of urban centers, along with the loss or depletion of their centralizing functions; the breakdown of regional economic systems; and the failure of civilizational ideologies." All these definitions have similarities, but based on research on the Classic Maya and the Western Roman Empire, two of the most famous collapses, and often a focus of many discussions about collapse (Middleton 2017), Storey and Storey (2017: 11–12) include the new concept of *slow collapse*:

> We define collapse as a major disjuncture in the trajectory of a complex culture (those commonly called "civilizations"); the political integration completely fails, and the Great Tradition (the assemblage of material culture and reflected ideologies unique to that culture) similarly comes to an end. That process also entails human suffering on a large scale, largely through diminution of population, which almost never does mean total disappearance of a population; but there is significant loss of life and a smaller population left behind. The people (in most cases) survive, persist, and regenerate into another complex society; usually there is a gap (large or small) before re-establishment or re-integration of complexity into a new political system with a new Great Tradition, which is partly derivative of the old but also distinct.

Collapse is not necessarily abrupt or quick because it can take several centuries for the depopulation and loss of elite Great Traditions to occur. All cultures possess Great Traditions, but complex societies incorporate various institutions that reproduce a mass of the material and cognitive elements in sufficiently numerous quantities to make it easy to recognize the elements of the Great Tradition unique to that culture. Webster further noted that, loosely, one can speak of a variety of cultures as "civilizations." "It is only fair to say that we are still most likely to label as civilizations those complex societies (they must be state-level and urban societies also) that manifest such qualitative elements in complex, durable, and grandiose ways." He also adds that ". . .things collectively comprise what we call Great Traditions, which were heavily associated with the elites of ancient civilizations" (both quotes Webster 2002: 67). How a Great Tradition changes after a collapse is relatively easy to discern, as well as how successive Great Traditions evolve in a related fashion in one place. Figure 1 shows deities and "divine" emperors from the Greco-Roman tradition and how there is both continuity within the discontinuity of civilizations giving way, especially after the collapse of the heavily Hellenized Roman Empire.

In a rejection of the progressivist framework, it can be asserted that, contrary to the sometimes unintentional tenor of prevailing opinion, collapses are morally neutral. Collapse has occurred when, for a variety of reasons, a state-level institutional infrastructure has been weakened so irreparably that it ceases to exist. Weaknesses are identified in two major kinds of evidence. The first is human socio-cultural behavior in institutional settings (entailing human error and mistakes) that weakens cultural integration. The second is diminished human-ecological equilibrium (usually challenges to the extractive efficiency of human agricultural practices, possibly due to natural and anthropogenic climatic and environmental degradation). Both result in a net loss of energy that had been previously directed to the fulfillment of human societal ends.

The Collapse of Complex Societies, Fig. 1 Four images from Greco-Roman antiquity that show the progression of a Great Tradition; far left, the statue of Zeus in the Temple of Zeus at Olympia (virtual reconstruction by Dave Martenson); second from left, the Emperor Tiberius, a relief from Nijmegen, the Netherlands (Photo: Rob Mols): Roman emperors were often worshipped as deities in the provinces so this is like an image of a god; second from right, the statue of the 4 tetrarchs from S. Marks, Venice, originally from Constantinople: Roman emperors had long adopted quasi-divine representation (Photo: G. Storey); far right, the Christ Pantokrator from the cathedral of Monreale in Palermo, Sicily, showing strong links with eastern Greek iconographic traditions, but clearly inspired by the image of Zeus more than 1500 years earlier (Photo: G. Storey)

There are other terms in this discussion that require definitions: *resilience*, *sustainability*, *vulnerability*, *transformation*, *transition, and continuance*. Resilience has been defined as "the capacity of a system to experience a disturbance, and then return to its original state" (Jacques 2015: 50), while vulnerability is susceptibility to disturbance, affected by the "exposure and sensitivity to a particular threat" (Jacques 2015: 213). For anthropologists and archaeologists, resilience is not necessarily a return to original state; it is capacity to survive in altered form by adapting and transforming when faced with significant stresses (Faulseit 2016). Social transformation, transition, and continuance, which all suppose surviving a crisis and having to regroup in some fashion, are all really evidence of resilience but definitely do not indicate a "return to original state." Notable contemporary interest around collapse has been focused on sustainability, which involves maintaining present social systems and its benefits for future generations, and reflects worry about collapse and our hopes to survive it. All terms mentioned could refer to a wide range of social systems. Jacques (2015: 44), for example, defines sustainable societies as those with ecological accountability and restraint, justice for its own and other peoples, and foresight to avoid vulnerabilities. Jacques' definition indicates that attaining sustainability is not easy, furthermore suggesting that, in the end, the study of collapse does not provide much comfort.

Resilience and its opposite, vulnerability, have been integrated into a theory about the so-called adaptive cycles that societies (treated as ecologies) tend to follow. Those cycles resemble a reworking of the patterns of ups and downs that many archaeologists and historians have described for past societies (original cycle from Gunderson and Holling 2002). It begins with an *r-phase*, the period of initiation and initial development followed by a *k-phase*, which sees the maturation of a socioecological system and its attendant cultural traditions. It is a time of "intensification of production; increased management over, and investment in, a smaller number of key productive strategies; and hypercoherence, which means there is a high level of integration" (Iannone 2014: 10). We then see a time of rapid disturbance, destruction, and abandonment, called appropriately enough the omega-phase (ending), which leads to an alpha phase (beginning), characterized by rapid changes and restructuring. Vulnerabilities appear and build up during the k-phase, morphing into fully-fledged perturbations (often environmental but human as well;

Johnson's "social hubris," (2017) for example) which cause societies to either start again (if the response is resilience), entering a new r-phase, or they fail to cope and collapse, short-circuiting the cycle. That entire process provides a framework for understanding how societies make or avoid "mistakes," which can be applied not only to study of the past but also for critiquing current situations, all in the service of helping to "chart a better future for those who will follow us" (Iannone 2014: 11; see also Costanza et al. 2007).

Many traditional views of societal collapse clearly require revision in light of better information that has been gathered on the post-collapse periods of some of the most notable cases of societal collapse. Schwartz and Nichols (2006) provide cases. Cultural resilience is a useful and newly appreciated aspect of the question of societal collapse – our examples of the Maya and the Romans are good examples of such resilience and regeneration. The adaptive cycle of resilience theory (Redman 2005; Costanza et al. 2007; Faulseit 2016; Middleton 2017) has become a prominent paradigm in collapse studies. Figure 2 shows how it can work for the Romans and Fig. 3 shows the same for the Maya.

Societies Cannot "Choose"

One critique of collapse studies must be discussed here, especially in regard to Diamond's influential study (2005). Critics pointed out a problem even in Diamond's title: *How Ancient Societies Choose to Fail or Succeed;* societies are not the kind of entities that "do" things. Johnson (2017: 8) also anthropomorphizes "society": "the theme running throughout the book: the society that acknowledges and adapts to a changing world is the society that survives"; and of the Maya: "societies are generally conservative and seek to maintain a basic status quo…" (Johnson 2017: 63). Diamond's critics were right: societies cannot do these things and they should not even loosely be said to do them. Only people can do these things. Clearly, the people in charge are the ones that are responsible. But, as with Diamond's and Johnson's analysis we can ask: what is the message? Leaders mess up and do the wrong things, so do not take leaders too seriously? Given the nature of powerful governance and behavior of world leaders in state-level societies, that message is not particularly comforting.

Consequently, careful consideration must be accorded the concept of *agency* (a favorite issue

The Collapse of Complex Societies, Fig. 3 The Classic Maya in the resilience analysis model. (Drawn by G. Storey)

in archaeology currently), which must be taken up in terms of the distinctions of who has the power to do what, between elites and commoners. However, the current formulation of blaming the elites smacks of something that William T. Sanders complained of incessantly in writings about antiquity: treating the past as if it were subject to "the Great Man Theory of History." Although historians never really formulated such a theory, it has been easy to acknowledge that a great deal of history has been written that sounds suspiciously as if Great Men *were* the key. At any rate, giving individuals too much credit may be a real problem, given how archaeologists focus as much on the evolution of complex societies as a process, as on individual actions. On the other hand, in our own recital of the role of individual rulers (Storey and Storey 2017: 108–133), compared to Johnson's (2017) setting out of the features of social hubris, one has to admit, yes, much of the "blame" can be laid at the feet of the elites in control.

A distinct problem with trying to promote a general theory of collapse is that those who do that are doing what used to be called "universal history" which puts them at a distinct disadvantage. Many do not really approve of that kind of work in academia: "in recent years – largely due to the postprocessual critique – comparative diachronic studies of the sort we are attempting, with a focus on developmental issues, have frequently been avoided in favor of synchronic analyses of individual societies and their historical specificities. But a total abandonment of the comparative diachronic would be misguided" (Schwartz 2006: 5). One reason for that is because, once one specializes in the cultural residues of one region, one is expected to master a staggering amount of detail and then be able to quote it chapter and verse when called upon to do so. However, anthropologists should be more tolerant of this kind of approach than they sometimes demonstrate. After all, anthropologists have considered it perfectly acceptable to study Chinese civilization and culture and draw conclusions about the overall trajectory of human endeavor as represented in Chinese culture. It is freely admitted that the anthropologist who does so can never be as knowledgeable about China as a full-blown Sinologist, but that is precisely the point. The Sinologist sees only the trees of China, while the anthropologist sees the forest of all human complex cultures and can thus accord China its proper sphere as a comparative exemplar of how a single human culture can be configured.

The consensus of collapse researchers for some time has been that collapses are not caused by one

single cause, but by conjunctions of vulnerabilities in politics, social organization, economics, and resources (e.g., Webster 2002; Middleton 2017). The effects of environmental degradation caused by human intensification of use, plus large effects from climate change, have become more prominent as important underlying vulnerabilities. There are already published works where archaeologists and paleoenvironmental scientists have collaborated to study how socio-natural systems respond to perturbations. The list includes *Which Way the Wind Blows* (McIntosh et al. 2000), *The Archaeology of Global Change* (Redman et al. 2004), *El Niño, Catastrophism, and Culture Change in Ancient America* (Sandweiss and Quilter 2008), *Sustainability or Collapse? An Integrated History and Future of People on Earth* (Costanza et al. 2007), and *The Archaeology of Environmental Change: Socio-natural Legacies of Degradation and Resilience* (Fisher et al. 2009). Thus, this is a very dynamic area of research, offering the prospective researcher an opportunity to be part of interdisciplinary discussions and cooperation.

Jared Diamond (2005) has successfully combined academic and popular writing, through "big picture" human history, tackling the subject of ends or collapses in his book (he also calls some of them "vanishing" societies). He uses some of these cases as "lessons" that might apply to the modern situation, even though he is careful to clarify how modern societies are different from past societies, in ways that both decrease and increase risk of collapse (2005: 8). Environmental damage is paramount in all of Diamond's examples, and climate change looms large in most as well. Diamond applies a comparative method investigating how societies collapse and what influence particular "input" variables had on the process. He defined five factors that appear to be generally implicated in his examples of past collapses: negative human impacts on environment, adverse climate change, presence of hostile neighbors, lack of trade partners, and the trajectories of decisions taken impacting on how the societies adapted or failed.

Thus, exactly what does Diamond mean by "collapse"? The underlying similarity among all his examples is that when things are good, populations grow and expand their use of the environment. Above all, that means people "choose" to bring less favorable lands into agricultural production. These lands are less favorable because of their lower productivity and greater vulnerability to erosion and overuse than prime lands. As these lands are damaged, they are abandoned, and the society can no longer support the large numbers of people that have come into that society. A great deal of conflict and violence ensues, leading to a demographic crash, but in most cases, remnants of the population survive along with much of their culture. What seem to have been lost were those elites/rulers who were more interested in consumption and prestige, and who were unwilling to give up some privileges in the face of mounting scarcity. The culture and the peoples continued on, sometimes in smaller territory, sometimes in the same place with smaller populations, but always with less highly developed political institutions and less economic specialization/integration.

Even before Diamond, anthropologists/archaeologists and climatologists had started to try to answer climate change worries by showing how humans have already responded to changes in their environment, including climate change (McIntosh et al. 2000). These authors criticize the short-sightedness of contemporary views, as if the past cannot teach us anything, and the lack of social science understanding of how humans perceive and adjust to climate and environmental problems. Humans have perceptions of nature and act according to these; the importance of social memory of how to react, especially on local scales, must be respected (McIntosh et al. 2000). Using what anthropologists and archaeologists already know, instead of just simplistically attributing catastrophic effects to past climate changes, can help us today understand our human capacity to adapt. McIntosh et al. (2000) were trying to bridge the climatology/social sciences divide, but Diamond (2005) did not reference it.

Robert Dunbar (2000), a paleoclimatologist, pointed out that known climatic events have different geographic and time-periodic scales, and Jeffrey Dean, an archaeologist, also noted this

different periodicity in the prehistoric Southwestern USA (2000: Fig. 2.2). In both cases, they pointed out that more common events can be adapted to by human societies, although Dean also cited population size and societal complexity as influencing adaptability. Dean noted that once large populations and hierarchical societies developed, many areas were abandoned during periods of climatic stress. Rare stressful climatic conditions can make it difficult for humans to adapt. These two authors provided general conditions that can be useful in correlating climate change and collapse: these include the rarity of a climatic situation and the large size and complexity of the society trying to adapt.

Caldararo (2004), a biological and medical anthropologist, wanted to use the past to discuss the future of humans and hoped that his book would be of use to non-anthropologists. His *Sustainability, Human Ecology, and the Collapse of Complex Societies* focused on complex societies: how they put so much pressure on resources and the environment, make irrational economic decisions, and thereby cause human institutions to fail to adapt. Humans should always be aware of the historical and ecological problems of the past and should try for sustainability. Like Diamond, Caldararo used Japan as a positive example but like Diamond, underestimated how global connections might have provided mitigating outlets for the problems faced, as wealth allowed the contemporary Japanese to displace environmental limitations by importing needed resources. Also, the earthquake and tsunami of 2011 in Japan have revealed how vulnerable modern societies are to extreme natural disasters, despite extensive global assistance networks. Caldararo used Tainter (1988) as a guide for explaining that the costs that cause the collapse of complex societies can improve life for the survivors. Caldararo tries to cover too many subjects to formulate a coherent argument, such that a variety of different economic lessons can be learned from the Roman Republic and Roman Empire, in our opinion. At the end of Caldararo's book, it is a smaller population and reduced consumption that seems to be the most important factors for avoiding collapse. Achieving sustainability is something he believes humans can do, but he also fears that collapse will happen.

Sustainability and human-environmental relations are also the subjects of *The Archaeology of Global Change* by archaeologists (Redman et al. 2004). In their introduction, the editors discussed how archaeology can shed light on how humans impact their environments and thus affect the sustainability or collapse of their society. It is common for societies to be sustainable for some time and then go to collapse. Redman et al. (2004) stress that human actions have significant effects. It is not just climate change that causes problems, and complex societies and large populations can be sustainable for centuries or millennia. However, deforestation and the ensuing soil erosion, plus the pressure to produce more food and get other resources needed for such societies to continue, can eventually lead to "overutilization" of the environment in many cases. Environments can regenerate, but if the degradation is too severe, it may take too long for the environment to recover for human purposes, as we think happened in much of the Maya region.

Brian Fagan (2004) is an archaeologist who writes books for a wider audience and is interested in how environment and climate change have influenced human history. In *The Long Summer* (2004), Fagan studied how the vagaries of climate change have affected civilizations, focusing on fluctuations of warming, cooling, rainfall, and drought over the last 15,000 years. Over this period, there has actually been a fairly stable period of prolonged warming (the most stable in the last 400,000 years), which has benefited humans and made possible the ever larger and more complex societies that characterize human history since circa 10,000 years ago. As the contemporary pattern of global warming continues, the problems facing humans are increasing because we have become more vulnerable to climate change. Fagan's larger point is that as societies become larger and more complex, they also become more vulnerable to disruption and collapse, echoing Tainter (1988).

Focusing on El Niño weather as a catalyst for producing catastrophic events to which humans must adapt, the collection by Sandweiss and

Quilter in *El Niño, Catastrophism, and Culture Change in Ancient America* (2008) features paleoclimatologists and archaeologists discussing the interaction of natural events with human change in the Americas. Sandweiss and Quilter are interested in large-scale changes, where it appears that natural forces were important. Humans have varied reactions to sudden events, and archaeology is good at showing and tracking such responses, but it is nevertheless difficult to understand the human agency involved. Humans are neither purely victims of nor totally immune to disruptions from natural forces. The key to positive outcomes seems to be flexibility to adapt, perhaps an echo of Diamond's "choice," and a more optimistic outlook. Sheets (2008) provided illustrative case studies in the volume, in which he showed that, in the face of explosive volcanic eruptions, some societies are resilient while others are not. While people certainly do learn from these catastrophes, Sheets, like Fagan, concludes that in general the more complex the society, the less resilient it proved to be.

Fisher and colleagues Niño (*The Archaeology of Environmental Change: Socionatural Legacies of Degradation and Resilience*, 2009) agreed with Diamond that the past has many episodes of natural perturbations with human factors that caused social decline. However, to them, Diamond is too fatalistic in his approach, as such declines have complex and varying explanations. Socionatural archaeology, as they term it, involves landscape, land use patterns, and the history of those anthropogenic environments, providing useful information for current crises. Success or failure is due to more than just demographic or climatic change. Degradation of land can occur just as much from failure to keep up expensive modifications, such as terraces and irrigation systems, as from overuse, for example. In their conclusion to this volume, Hill et al. (2009: 256) point out that "the unpredictable, unintended consequences of human action loom large in causing past environmental problems." This is a response to Diamond's contention that societies "choose" to fail. And there are no simple cause-and-effect factors. The past presents many useful examples of the outcomes of the myriad connections between humans and environments that can inform present policy. That volume chooses to stress the general resilience of humans.

While there have been such environmental explanations since the dawn of collapse studies, these recent studies illustrate the change in knowledge supporting this trend, as it is only recently that it has become possible to successfully integrate paleoenvironmental global changes with human history (Costanza et al. 2007), due to improvements in dating of paleoenvironmental events. There is recent interdisciplinary cooperation between social scientists, including archaeologists, and environmental scientists, to study the history of human societies. It is the interaction of environmental adaptation and human societies, including the effects of climate change, which are being investigated. Such an approach illustrates a stronger understanding that human societies, and especially complex ones like civilizations, are extensively affected by ecological and climatic factors. One cannot separate human institutions and cultural understandings from the environmental/ecological systems with which they are intertwined. The terms "socioecological systems" or "socio-natural systems" are the focus of study. The concern is obviously with how societies adapt to change and avoid collapse, a relevant concern today. The temperature regime of the last 2,000 years (Fig. 4) shows some major climatic shifts that can be correlated with notable cases of collapse. Although not a sole cause of collapse, the environmental factors are relevant and highly contributory to cultural trajectory downturns.

Also, archaeologists are able to work at various levels by integrating adaptive cycles from household to region, allowing the investigation of the integration and vulnerabilities at those different levels. Concerned with the vulnerability that leads to collapse, archaeologists are interested in discovering what socioecological system characteristics might lead to problems, such as increasing complexity or intensifying production, in reaction to climate change or other perturbations. As Tainter (1988) demonstrated, the problem-solving which helps at one point may become one of the vulnerabilities later, as the institutions

The Collapse of Complex Societies, Fig. 4 Multi-source record of temperature for the last two thousand years, showing distinct cooling of temperatures and the slow collapses of several complex societies. (Adapted from Ljungqvist 2010: 345, Fig. 3)

and practices become more costly and less flexible. Then a major disturbance, such as environmental/climatic change, may combine with the less flexible, or more rigid, system and bring on reorganization or collapse. Societies will vary in their capacity to respond to change, but the determination of the resilience of problem-solving behaviors and institutions, again linked to the various levels of the adaptive cycles, will allow the discovery of the regularities present in those that survive versus those that collapse. For resilience theorists, there is no simple reaction of a society to climate change; instead, there are particular decisions and historical trajectories, but the search should be for the sources of resilience and vulnerability.

The Roman Empire and the Classic Maya

Among many Roman scholars, especially, there is a turning away from the terms such as "decline" and "fall" because they are too "loaded" and prejudicial to the conclusions to be drawn about the character of the late Roman world. Terms such as *transformation*, *transition*, and *continuance* are preferred. Those terms are usually not formally defined, because their advocates seem to believe they are self-explanatory. To some, there is so much conceptual baggage and preconception associated with the concept of decline that it really is a hindrance to further study of the Roman Empire and thus is "no longer needed" (Whittow 2001: 243). Cameron argues forcefully for characterizing what happened during the later Rome Empire as something as simple as "change" rather than "decline" or "collapse," or even serves as an example of "transformation" (Cameron 2011: 211, 210, 212). Some Romanists clearly mean to depict the events of late antiquity in as neutral a light as possible.

Peter Brown, credited with turning the interpretation of the end of the Roman Empire as one of a transition rather than a decline and fall (Brown 1971), has reiterated arguments for transition: "The western empire was not so much destroyed as *eroded*. . ." and "It is quite possible for a society to *unravel*." He also tempered his arguments with the admission that things were bad in the transition: "It would be unwise to ignore many of these catastrophes." However, his tone is that the end of the Roman Empire was not a catastrophic change. It was a "silent change" without "catastrophic drop in the standard of living. . ." (quotes Brown 2013: xxvi–xxvii, xxxii, xxx, xxiii, italics ours). The denial

of a drop in the standard of living is quite debatable (see Ward-Perkins 2005).

One British Roman archaeologist, in the context of late Roman towns in Britain, used terms such as "vitality" and "creative and vibrant" (Rogers 2011: 163, 165, 177, 176) to describe post-Roman urban activity. Such terms are as emotive, controversial, and perhaps as biased as "decline" – how does one define "vitality," and might not its definition be as much in the eye of the beholder as "decline"? Middleton (2012: 264) correctly regarded that "these [terms] can be equally controversial and value laden." However, it is still a fair reading of the evidence to conclude that there was a major "Things Fall Apart" (to borrow the title of Chinua Achebe's novel) character from fifth- to seventh-century CE life in the Roman world. Numerous archaeological studies of late antiquity (Storey and Storey 2017: 42–28, Table 3.2) have demonstrated that the economy remained prosperous in several places in the Roman Empire, but that after the fifth, sixth, or seventh centuries CE – depending on the region – that economic prosperity was lost over the majority of the territory that had once been the Roman Empire. Romanists themsevles cannot avoid characterizations for this period that use the otherwise objectionable terms such as "decline," "erosion," or "unraveling."

Only a couple of illustrations of the impossibility of avoiding the objectionable terms are in order. Speaking of the west coast of Italy, we are told, "a clear *decline* in material wealth can be seen from at least the sixth century." Regarding the Eastern empire: "it has been deduced from a study of settlement patterns in the region that while settlement density reached an unprecedented peak from the fourth to the sixth centuries, from the seventh century there was a *dramatic fall* in occupation." And: "If we put together the evidence from archaeological investigation of sites very widely scattered round the Mediterranean, *a general picture seems to emerge of contraction*. . ." That is followed by the statement that "the west, where urban life seems to have been *in decline* already by the late fifth century" (Cameron 2011: 156, 158, 151 two quotes, italics ours). The general archaeological picture of the Roman Empire, both west and east, is of eventual contraction. It seems reasonable to conclude that "general contraction" is not that different from a "decline," that certainly entails demographic loss.

So, it does not seem entirely reasonable that the concept of "decline" or "collapse" must be abandoned; they are both far too well-established as concepts to simply discard because people think they are too "negative." The two approaches under discussion here have been labeled *catastrophist* and *continuist* (Cameron 2011: 209; roughly equivalent to our initial setting out of traditional and new approaches to collapse). Even those who abjure the dichotomy, generally argue more in line with the continuist approach: "Much too much emphasis is still placed on the 'collapse' of the Roman Empire and the 'transformation' of the classical world, and too little on the long-term continuities" (Cameron 2011: 212). But, one need not treat "decline" as an entirely negative term. In purely neutral terms, it simply indicates a loss of energy and integration in a cultural system, even when used by those, like us, who may be arguing the catastrophist approach more.

A great deal of research into late antiquity in the last half-century has aptly demonstrated that the post-Roman world was definitely not a "dark age" and showed much elaboration and complexity. That emerging picture has urged its researchers to argue that the terms "decline," "fall," and "collapse" should be de-emphasized, if not abandoned outright. It would seem more reasonable to suggest that all terms in the debate need to be refined to where they are useful and that when one term is used by one investigator, he or she must make clear what is meant by its use: "The onus is on writers to indicate clearly what they mean by collapse and not to confuse or abandon the concept" (Middleton 2012: 268). Usefully defined, "collapse" must mean a loss of complex integration on a macro-scale. If you have a regional (world-system size) empire, and it is replaced by a host of unintegrated kingdoms (as happened to the Western Roman Empire) that is a clear case of loss of complexity that can correctly be described as a "collapse."

Consideration of one explicit change in terminology, promoted by those who do not like the

terms decline or collapse, allows us to observe that the suggested changes bring little benefit. Horden and Purcell (2000: 263–270) recommended the terms "intensification" and "abatement," adapted from LaBianca (1989). The former refers to periods when agricultural exploitation is increased and energy inputs and returns are high, while the latter refers to periods when exploitation recedes and less energy is put into production with consequent decrease in returns.

It is useful, however, to consider how these terms were developed for a different context, an early Iron Age context in which subsistence lifestyles were still in flux. LaBianca explicitly stated: "sedentarization is specifically linked to intensification and involves households becoming increasingly oriented toward crop production. . .nomadization is typically linked to abatement and involves households converting to more pastoral, more nomadic modes of existence" (1989: 171). Those advocating this model should consider whether they mean actually to advocate a major turn to pastoralism in the wake of the fall of the Roman Empire (or the collapse of the Classic Maya, or most other cases of collapse). Regarding the later Roman Empire and later antiquity, however, there is no question that sedentary occupation and agriculture had been the rule for more than two and a half millennia, and continued as the dominant subsistence pattern. Thus the original conception of the term abatement seems much more compatible with collapse than it does with continuity or transformation. After all, what *does* happen in major abatements? It is likely that large numbers of small farmers at best struggle and at worst starve, leading to demographic decline. LaBianca cited the problems associated with food shortages and epidemics (1989).

Advocates of the new terminology argue that intensification is not a process that occurs only in times of prosperity and that abatement is a normal part of agricultural exploitation, comparable to letting land sit fallow in slash-and-burn agriculture. The point is that LaBianca's description of abatement (1989) is not at all as benign as the equivalent of merely letting some land lie fallow. Some also further argue that the "declines" in urban and rural residential patterns in late antiquity should be understood as the normal ins and outs, and ups and downs of the cycles of intensification and abatement of agricultural exploitation (Horden and Purcell 2000: 263–266). But in the same way that the term "economic downturn" is a euphemistic characterization of those times when many people get really hurt, this whole argument about whether or not terms are too negative or not seems misguided.

One lesson to be drawn about using intensification and abatement as the preferred terms is that most complex societies have gone through cycles during their periods of *floruit*. A friendly amendment to the resilience theory dynamic is presented in Fig. 5 (for the Romans) and Fig. 6 for the Maya. Instead of the round and smooth ovals of the original in Figs. 2 and 3, the revised figures show a circular profile with many jagged edges. The trajectories of complex civilizations are messy. Differing and random-shaped "perturbations" can interfere with a smooth transition from one state to the next. Civilizations are full of ups and downs, and ins and outs; their trajectories are a mosaic of micro- and macro-variations that indicate that at any one time, one part of the system may be prospering while another part is struggling with challenges, or caught in stasis.

One can accept that the terms intensification and abatement can be used to describe this mosaic, or bumpy pattern. However, there comes a time when the situation does not return to an equilibrium that is on the steady course of the oval of the resilience cycle – the socio-political system in place is not confirmed. It is better to call it a collapse, when basically there is no reversal of the abatement. The original use of intensification intended to describe a revolutionary transformation of major subsistence patterns – agriculture is adopted (intensification) and then there is a return to nomadism (abatement). Perhaps the major transformation does not have to be as radical as the abandonment of agriculture (that did not happen with the collapse of the Roman Empire or the Maya), but the key is that change is radical and the existing system is "abated" out of existence. Regeneration may be rapid and produce a culture

The Collapse of Complex Societies, Fig. 5 Revised resilience cycle for the Roman Empire. (Drawing by G. Storey)

similar to its predecessor (resilience), but there has been a major ending with a new beginning. A collapse has taken place. If one defines intensification and abatement as analogous to the bumps in Figs. 5 and 6, that may be acceptable. But the attempt to provide a replacement to the terms generally employed is like chasing the proverbial chimaera. People simply must explain what they mean by their use of terms clarifying the positive and negative implications.

Perhaps due to the common Romanist rejection of the previously accepted decline and fall from Edward Gibbon, a new hostility towards collapse has begun to appear in archaeology (see especially *Questioning Collapse*, McAnany and Yoffee editors, 2010a). Many scholars focus on human resilience, especially as illustrated by the survivorship of peoples, and the fact that people and cultures do not completely disappear (something acknowledged by virtually all collapse investigators). Some argue that there is too much focus on successes or failures of past societies (a much-expressed criticism of Diamond 2005). Furthermore, in accordance with modern anthropological post-colonial criticism, many correctly point out that the effects of colonialism have been underestimated in some cases of collapse. Lastly, cases of collapse have involved peoples who have been subjected to glaring inequalities, due to racism and prejudice. It has also been suggested that collapse is a bankrupt concept because it suggests the total disappearance of peoples and cultures, in a manner inappropriately analogous to biological extinction (McAnany and Yoffee 2010b). However, virtually no collapse specialist, not even Diamond (2005), can be fairly accused of advocating that version of collapse. Some investigators are also hostile to explanations that blame rulers and societies for ecological problems. That is a reasonable view, except that, as previously noted, it must be acknowledged that elites have played major roles in exacerbating the "perturbations" that affect complex societies, weakening a society's ability to cope with problems when they arise.

Our review of terminology brought up many of the issues related to collapse that have influenced the debate on the case of the collapse of the Roman Empire. It is appropriate to examine another famous case, the Classic Maya Collapse, which is still a focus of research and discussion. Perhaps the best thing that may have come out of all the hype over the ending of the Long Count calendar in December 2012 was that probably more members of the general public have become aware that the Maya did not disappear

The Collapse of Complex Societies, Fig. 6 Revised resilience cycle for the Classic Maya. (Drawing by G. Storey)

with the Collapse, as seemed to have been a widely held misapprehension. Nevertheless, the "mystique of the Maya" has been driven by their failure to maintain their civilization, which has left some of the most atmospheric ruins known from the ancient world (Fig. 7). The Late Preclassic and Classic Maya are the ones that left the most impressive remains, while the Postclassic remains are not as well-appreciated because those sites were relatively smaller or had been largely swallowed up by the Spanish during the Colonial Period.

As we enter the second decade of the twenty-first century, however, certain aspects of the Collapse – especially that is now frequently placed in quotes as "Collapse," to flag that it might not have really happened – seem to have become clearer. Most importantly, it "presents a very complicated, messy problem, rather than a nice, neat, sudden, and uniform cultural catastrophe" (Webster 2002: 216). In order to make the Maya Collapse clearer, it is useful to briefly review what features define the Classic Maya. Maya civilization had both a lowland and a highland component. The lowland component, the focus here and in most discussions of the Collapse, covers the Petén region of Guatemala, the Yucatan Peninsula, Belize, western Honduras, and parts of El Salvador, constituting the central core during the Classic Period (circa 250–1000 CE). The largest and most elaborate centers and densest populations were found here and these were the polities that collapsed.

The apogee of Classic Maya civilization occurred during the Late Classic period (circa 600–900 CE). The territory of the Maya was covered with numerous centers; some were very large and imposing, and there were many smaller centers close to the larger ones, resulting in a dense population of house mounds and plazas for the residences of the farmers in between the centers. Divine kings or their appointed governors and allied nobles ruled the centers, dominating a large population of farmers and retainers. The latter constituted probably no less than 80% of the entire population, much like other agrarian civilizations of the ancient world (Webster 2002). The elites commissioned sculpture and inscriptions, decorating the centers with dynastic lists, important life events, rituals, and war exploits of rulers. They used the Long Count Calendar to correlate their cosmological concepts and the rulers themselves to human affairs. The Long Count counted days since a mythical creation date (known to be a day in August of the third millennium BCE), inasmuch as the Long Count Dates have long been translatable into the month,

The Collapse of Complex Societies, Fig. 7 Partial view of the Great Plaza of Tikal, one of the largest of the Classic Maya centers. Temple 2 is in the center with the stelas and North Acropolis buildings to the left. (Photo by R. Storey)

day, and year of the Gregorian calendar (Morley 1915). The Long Count was one of the most distinctive features of the Classic Maya. The imagery of royal and courtly life, with its associated elaboration of temples, palaces, fine pottery, and ornaments in exotic materials, such as jade and marine shell, constituted the Maya "Great Tradition" that is so admired today. Despite possessing large population centers, Classic Maya society was never politically unified. Similarly to the Greek city-states, each center and its ruling dynasty had autonomy and its own history in its immediate territory (Nichols and Charlton 1997).

In the eighth century CE, the number of dated monuments reached its maximum and then stopped abruptly at various Maya centers, a process that took place in the ninth and continued into the tenth century. This cessation of the centers was very discontinuous; some centers disappeared early while others hung on for a couple of centuries more (Webster 2002). So variable and drawn out was this process that the entire period is now called the Terminal Classic (circa 800–1050 CE), varying in length depending on which parts of the lowlands were involved. The basic pattern entailed a beginning in the western lowlands and from there diffusing into the southern, central, and eastern lowlands of Mexico, Guatemala, Belize, and Honduras; some sites in each area survived for a time, bucking the overall pattern. In the end, many sites of the inland northern Yucatan peninsula were the last to become prominent and then, in their turn, were abandoned in the tenth and eleventh centuries (Storey and Storey 2017). There is evidence of population movement into surviving areas, but as yet, those indications are insufficient to account for the population of several million, now known to be present during the Late Classic, as mostly moving into new areas (Storey and Storey 2017). The main casualties of the collapse were the population, which decreased dramatically, and the type of rulership, "the Holy Lords," and the way it had been represented on buildings, monuments, and on other media during the Classic Period.

The Maya did not disappear completely, and there were rulers and a noble class of elites when the Spanish arrived; there were even a few sites remaining in what had been the Classic period "heartland." However, no longer were those sites festooned with stelae detailing the history of the dominant rulers and their ritual concerns and other art forms commissioned by them. The Long Count was all but gone, and calendrical information was much shorter with a shallow time depth. Generic depictions of deities and warfare, plus less personalized records of power holders (even possibly some forms of corporate governance) seem to have become the rule. The abandonment of both major and minor centers, including their supporting commoner populations, proceeded in tandem with this cultural shift. The region remained mostly vacant until only the past couple of hundred years. The Postclassic Maya (twelfth to sixteenth centuries) occupied mostly the Yucatan and Belize coasts and along a couple of major rivers, in seemingly smaller and more compact settlements than what had been in the "heartland" of the Classic Maya.

Of course, the modern Maya are still with us, and they represent a vital regeneration of Maya lifeways, but their recent lifeways are distinct from those of the ancient Classic Maya. Among Mayanists, there is some focus on the peoples who are alive today who survived the supposed collapse of their ancient forbears. Some Mayanists come close to asserting that use of the concept of collapse is ethnocentric, prejudicial, and detrimental to the living remnant peoples of the cultures in question. Somehow, it hurts a people's self-esteem to accuse their ancestors of having "collapsed." That argument is very unsatisfactory, and there is one counter-example that should put it to rest: the Romans. For peoples who have faced racism and exploitation by Europeans, such as the Maya, their descendants must be defended from the charge of a collapse – as if such a charge demeans them. No such argument is made for the Italians, probably because they too became a colonial people, long after their Roman Empire collapsed. There is no need to defend Italians from the negative connotations of the collapse of the Roman Empire. The message is unpleasantly clear: the Romans were first world exploiters for their time, as were their descendants in their time, and therefore not worthy of defense as a people who should be cherished and protected, and as victims of colonialism. There is something of a double-standard at work here.

In agreement with numerous other scholars, we think that neither the end of the Roman Empire nor the end of the Classic Maya polities were a "transition," nor that the question is about optimistic or pessimistic views of cultural evolution, as many in the debate claim (Storey and Storey 2017 *passim*). Change is the most basic fact of evolution, both biological and cultural, and all changes can be considered "transitions." However, transitions in cultural evolution are rarely neutral; many are quite dramatic, even destructive, and it is the ones sufficiently destructive so as to disrupt established lifeways to the point of diminishing the number of humans in the group – it is these changes that are often characterized as collapses. McNeill (2010) points out that there is often an element of arbitrariness in the choice of examples of societal collapse. It is reasonable to summarize that one is dealing with a collapse when lifeways change extensively and many people die.

Anthropologists who accept that critical cultural relativism is relevant to the study of ancient civilization must face the reality of massive loss of human life that collapses seem to have entailed. Collapse per se is not a moral issue. An institutional edifice collapses and loses energy production and consumption. It is not a moral failure; it is not a "bad thing," with the members of a culture being culpably responsible. But it is possible to assign blame for the mistakes made by individual agents, usually elites and rulers in control. Their mistakes are highlighted because their errors weakened the structure, not because they themselves were evil or perverted. It should be pointed out that current study of many collapses have found that environmental/climatological issues are of greater significance than may have been appreciated in the past (Storey and Storey 2017: 167–203; Johnson 2017: 189–210), thus diminishing the responsibility of agents, except to lament that their responses to the crises were

inadequate – an obvious lesson from which modern policy makers might well profit.

As a final illustration, long-term research programs in Precolumbian Mesoamerica, on societies that, in essence, collapsed, are relevant. One program involves the earliest mega-city in Mexico, Teotihuacan, the home of the pyramids just north of Mexico City, which probably had a population of 80,000–150,000 at its peak (Middleton 2017). Teotihuacan was the most powerful state during its heyday (circa AD 1-600/650), whose influence was felt all the way to the Maya area of the Yucatan Peninsula and Guatemala. The typical residence was an apartment compound of 60–100 people. Only a few of the probable 2,000 that were present have been excavated. Widmer and Storey (2017) excavated the apartment compound Tlajinga 33, a lower-status residence of full-time craft specialists. Consideration of the integration of this residence into the market economy of the city plus the health and diet available to these individuals within the urban environment have been major features of that research program (Widmer and Storey 2017). The status and health of these residents, although not their diet, seem to have deteriorated during the 300-year occupation of the compound. That stark reality indicates that Teotihuacan society was almost certainly on a downward trend, with increasing competition from nearby societies, when it became a probable victim of what is called the 536 AD event (Dull et al. 2010). This was probably the eruption of the volcano Ilopango in El Salvador, which affected global climate and many other civilizations (including Rome and China). Around that time, the ceremonial/political center of the city was burned, and the area abandoned soon after. However, by then Tlajinga 33 had probably already been abandoned for 30–50 years (Storey 2006). A recent survey has found the multiple probable causes, including climate change, environmental limits to food produced, the competition from rising nearby centers, and political conflict and revolt within the city (Middleton 2017).What happened and why it was not sustainable is the big question. That this was a collapse and not a mere transition seems undeniable, although the area continued to be a large settlement without the earlier urban character until the time of the Spanish Conquest.

In the end, the study of cultural collapse functions as a proxy for the evaluation of the anthropological concept of the state. The state is as old as the first primary civilizations, and then there were secondary and tertiary civilizations and states, virtually all of which have passed on as noted previously. Most early states were city-states, but neither city-states nor ancient nor subsequent modern nation states have been permanent. So, the continuation of modern nation-states is not an assured fact. Almost all ancient civilizations have long ago transformed themselves into entirely new entities, if generally continuing as state-level societies. That impermanence alone may account for the continued interest in the question of cultural collapse. The debate continues because nearly all state-level power holders must wonder how long state-level societies can last. Is collapse the fate of all complex cultures? That is the real question facing all state-level societies, which are the only alternatives in the modern world. To summarize: the current consensus is that collapse is a complex phenomenon, involving a variety of factors and reflecting particular historical circumstances. A recent book by archaeologist Guy Middleton (2017: 365) reiterates that there is a complexity of causes but also that there is loss of material and non-material culture, especially that related to rulers and elites, and that people and cultures do continue. Thus, power-holders might worry, but current consensus is that collapse is real – but there is life beyond collapse.

Colombia, Historical Archaeology of

Wilhelm Londoño Díaz
Facultad de Humanidades, Programa Antropología, Universidad del Magdalena, Campus San Pedro Alejandrino, Santa Marta, Colombia

State of Knowledge and Current Debates

In Colombia, the history of historical archaeology cannot be understood without the relationships of this branch of archaeology with traditional archaeology. Obviously, defining what is "traditional" is not an easy task, but for the argumentative purposes of this essay, we can understand by "traditional" a practice of archaeology focused on the archaeological record of pre-Hispanic societies; such descriptions, as has been documented extensively (see Gnecco 1999), were made from the perspective of a historical-cultural archaeology, as was the case for most Latin American archaeologies. Though this may be surprising for many academics, unlike Central or Western Europe, archaeology in Latin America was always configured as a science that worked with the other, with alterity. As it has been described by various academics (Gnecco 1999), this made Colombian archaeology build an ideal other, an ecological and artistic indigenous, who was colonized and buried by the cannibals that were found by the Spaniards.

As in many Latin American countries, archaeology in Colombia was part of a process of institutional development that had to do with dynamics such as the regulation of pre-Columbian trafficking, the updates in educational reforms of a liberal nature, as well as the need to generate national narratives where indigenous people could be connected with a collective story (Gnecco and Ayala 2016). Thus, starting in the 1940s, which is the moment when the first archaeological excavations began to be financed by the Colombian State, archaeology is considered to be, solely and exclusively, an exercise in the registration and exhibition of pre-Hispanic materialities (Gnecco 1999). Under this premise, an account of the pre-Hispanic history of Colombian territory began to be considered, which implied fitting the stories of the conquistadores and chroniclers with archaeological materialities. From this equation there emerged the pre-Hispanic cultural map that until now is used by some archaeologists and is a basic piece in teaching History in Colombian schools. Likewise, this cultural map has allowed the construction of the network of gold museums of the Banco de la República, which indicates the power of this imaginary. As a result of these determinations, during most of the late nineteenth and early twentieth centuries, hundreds of

colonial sites were simply destroyed or ignored, because it was thought that their scientific value was null. That implied that the architectural reforms carried out after the end of WWII, an era in which great changes occurred in Latin America as a result of the integration policies of the region to the project of economic expansion of the United States in the 1950s, aimed to construct modern buildings on colonial buildings. It was under this policy that many historic centers were intervened, destroying large infrastructure works whose scientific and cultural value was inestimable. Of that policy of colonial footprints' eradication, which was not made to strengthen an anti-colonial or Creole identity, but was made to give way to architectural modernism, few colonial buildings were saved, and others, after conservation policies were applied after from the 1980s, managed to preserve their facades (see Campo and Padilla 2014).

In the same way, Colombia's first schools of archaeology, affiliated to the projects of ethnological institutes, sought to provide students with tools to find the vestiges of the tribes that had been described by the Spaniards as powerful and numerous. The consequence of this educational policy was that archaeologists trained themselves only to look for large infrastructure works such as villages and roads or great manifestations of wealth such as the search for sites with high precious metalsmithing contents. Even the famous French anthropologist Paul Rivet, who came to collaborate with the foundation of the National Ethnological Institute in 1941, complained several times that in Colombia only what was pre-Columbian was considered and that the authorities did not see anything relevant in the ethnological findings that were made, as the verification of the existence of linguistic horizons that related the indigenous communities of Colombia, with similar ones of Ecuador, Venezuela, Panama, and Costa Rica. In any case, what Rivet pointed out in his correspondence with other academics in Europe was that for the Colombian government only the monumental archaeological findings mattered (cf. Laurière 2008: 495).

This predilection for the pre-Hispanic made that, once and without applying hypothetical models to be evaluated by means of the archaeological record, Colombian archaeologists saw manifestations of social complexity with only a few scattered features such as certain funerary trousseaux with goldsmithing or village systems interconnected by road networks (Gnecco 1996). In fact, this predisposition toward the pre-Hispanic caused archaeologists to locate colonial findings as anomalies or alterations of original pre-Hispanic sites. What did that mean? That if the archaeologist found European pottery or pottery made around, or bathed in pewter, he would immediately think that it was necessary to decontaminate these sites in order to record only the pre-Hispanic occupation. This policy of handling the archaeological record that we could call the policy of archaeological purification generated, consequently, apathy for colonial material culture. This recurrent situation led to the period of the conquest being thought of as a process of population change where the Iberian culture replaced the indigenous culture and where archaeology was unnecessary because of the amount of written documentation that allowed, diaphanously, making a portrait of colonial and republican history at the present. Due to this policy, Colombian archaeologists were shielded from the possibility of understanding the dynamics of the conquest and the colony as a stage of negotiations, resistance, and exchanges susceptible to being evaluated through the archaeological record.

Regarding the predisposition to review only the pre-Hispanic sites, there are several cases that deserve a comment. In the 1950s, archaeologist Julio Cesar Cubillos (1959) excavated a site located in the urban area of Popayán, a city with important colonial remains located in a valley between the Andes and the Pacific Coast, in southwestern Colombia (Londoño 2011). In his report, Cubillos focused on the pre-Hispanic aspects of the site in such a way that the article he published in the famous Colombian Journal of Anthropology was entitled "*El Morro de Tulcán* (Pre-Hispanic Pyramid)." Analyzing that report, Cubillos states that it is an investigation requested by Popayán local council because the rains exposed the adobe structures that make up the pyramid. When making the classification of pre-Hispanic ceramics, using as features the shapes and decorations, Julio Cesar Cubillos culminates the ceramic typology he

presents with a list of "miscellaneous" where he describes some colonial earthenware and a colonial coin (Cubillos 1959: 279). At the end of his article, he presents a photograph of a colonial *botija* (earthenware pitcher), an artifact of Mediterranean origin common in America where olive oil and wine were packed, which was imported into America; these artifacts began to be manufactured in America in several places at those times (Rice 2010), but there is no clear consensus on the first places of origin up to the present. Without paying much attention to what kind of object it was, Julio Cesar Cubillos fulfilled the task of reporting it by means of a photo with the simple title of "fusiform amphora" (Cubillos 1959: Plate XVIII). Subsequent investigations carried out by Wilhelm Londoño (2011) made it clear that it was a *botija* eventually produced in the valleys of Moquegua in the eighteenth century and it was probably used to transport wine or grape brandy (*pisco*) to Popayán along the route that connected the ports of Callao (present Perú) with Buenaventura (on the current Colombian Pacific coast) (Londoño 2011). A peculiar fact is that the current cities of Popayán, in the Colombian Andes, and Lima, current capital of Peru, were connected by sea and not by land, and the connection was achieved because people in Popayán needed to import supplies to celebrate the Catholic Mass. It should not be surprising that the main and most needed product was wine (Londoño 2011).

In general terms, Colombian archaeology, in its beginnings, was a historical-cultural practice (Trigger 1989) that sought to rescue and exhibit vestiges, especially goldsmith objects of the powerful tribes that inhabited the territory of Colombia before the arrival of the Spaniards. As it has been diagnosed by different archaeologists, archaeology in Colombia was, until the 1990s, a practice of recollecting artifacts to enrich the showcases of institutions such as the Banco de la República and its museum network or the National Museum, ignoring completely what the native communities had to say about those materialities (Londoño 2012).

From its institutionalization from the 1940s to the 1990s, the practice of archaeology in Colombia was predominantly acritical, based on the premise that archaeologists should collect whatever data was at hand and then make a synthesis. In this sense, Colombian archaeology was captive of the prison of induction, a characteristic of cultural historical archaeology (Clarke 2014). The 1990s mark a rupture with this model because a series of reforms in the practice of archaeology began in the country, due to the initiative of several academics, including two Colombian archaeologists of great importance: Carl Langebaek and Cristóbal Gnecco. In the case of Langebaek, his contribution to Colombian archaeology was through the application of processual models to understand the resources' dynamics of centralization and redistribution in Bogotá savannah's chiefdoms (Langebaek 1995). For the first time, the idea of a given social complexity was questioned, and models were constructed to evaluate phenomena such as the relationships between settlement patterns and control of fertile lands. In the case of Gnecco, his work consisted in understanding the population dynamics related to the early settlement of southwestern Colombia (Gnecco 2000). Gnecco, applying processual theories of early settlement, succeeded in identifying patterns of consumption that showed communities that were not mere hunter gatherers but were active agents in the construction of orchards or gardens that supplied these populations certain nourishment. For Langebaek, it was clear that political power did not reside in the control of resources, and Gnecco showed evidence that the bands that early occupied southwestern Colombia were not only collectors but had vegetable management. Since the evidence that Gnecco provided were not meant to speak of agricultural systems but of manipulation of the environment, these communities were understood as being located in the middle between collectors and farmers. What is interesting here is that these two archaeologists were responsible for training a generation, in the 1990s, who could not simply ignore certain materialities such as colonial ceramics. Gnecco located in Popayán and Langebaek in Bogotá were responsible for the courses taken by much of the Colombian archaeology that led, for the first time for more than half a century, to lecture ceramic classification or

ceramic typologies in Colombian universities. Within this context, some ideas emerged that were soon taken seriously by Colombian archaeologists. One author who had a special emphasis on sensitizing scholars to the complexities of classification was Robert Dunnell (2002). As specified in Dunnell's work, typologies are the result of the choice of attributes that define the types. Consequently, classifying was not to fit ceramic types with ethnic groups; on the contrary, it involved conscious operations of choosing attributes that had temporal, spatial, or cultural senses that would allow archaeological inferences to be made. Dunnell's ideas were quickly accepted by various archaeologists (i.e., Londoño 2011) who quickly began to notice that certain pre-Hispanic techniques prevailed in the colony, in certain objects whose elaboration was the result of the fusion of peninsular with indigenous techniques.

Within this atmosphere of academic criticism, archaeology began to be questioned. In fact, despite the fact that in the United States in the 1960s the need for the establishment of the hypothetical deductive model had been discussed (Watson et al. 1971), it was only in the 1990s, in Colombia, that archaeologists began to discuss the need to abandon the descriptive paradigms to start thinking about the complexity of archaeological data construction.

In reviewing the information provided above, it is clear that the beginnings of historical archaeology in Colombia are related to epistemological changes that made the need to investigate colonial dynamics from the point of view of the archaeological record visible to various scholars. In this sense, the beginnings of historical archaeology are not directly related to the need to evaluate the complexities of the conquest and the colony but as the result of understanding materialities that repeatedly emerged in the excavations and were rejected or ignored by academics.

Within this epistemological effervescence, several researchers began to think very seriously about the ceramic classifications of the archaeological sites. It was in this way that it was possible to appreciate that the first archaeologists did not account for the ceramics that were purely colonial, because this would not make their site be considered pre-Hispanic. In addition to Julio Cubillos' anecdote mentioned before, in the 1960s the famous archaeologist John Goggin (1968) reported that the Colombian nationalized archaeologist, Gerardo Reichel-Dolmatoff, had offered him fragments of colonial pottery that he recognized as coming from an archaeological site in the center of Cartagena de Indias. The strange thing about Reichel-Dolmatoff is that, being one of the archaeologists that excavated most of the sites in Colombia, at that time, he did not officially register any colonial site.

This emphasis in thinking the dynamics of artifact classification in archaeology was the cause that, in the mid-1990s, many archaeologists began to look at certain types of ceramics that could be clearly classified as colonial. Within this awakening of historical archaeology, there were, at least, three main tendencies that can be distinguished for the Colombian case: (1) A trend of archaeology that focused on the investigation of the indigenous practices' permanence in colonial towns (Therrien 1996), as well as resistance practices in Afro-descendant communities (Mantilla 2007). Within this line of work, practices were registered through which the new pottery techniques brought by the Spaniards were used to manufacture objects with pre-Hispanic forms (Loboguerrero 2001). (2) Likewise, a large amount of imported materials was detected, and ceramic consumption patterns could be observed that indicated strategies of distinction between the colonial elites (Uprimny 2001) and republican elites (Gaitán 2001; Gaitán and Loboguerrero 2015). (3) Finally, a large amount of work emerged on old houses that were being remodeled in the framework of the gentrification processes that took place in cities such as Popayán, Bogotá, Villa de Leyva, Santa Marta, and Cartagena (Therrien 1999a; Therrien 1999b; Ome 2006; Campo and Padilla 2014).

In reviewing the consolidation of an archaeological agenda that investigates the colonial archaeological record, it is clear that its constitution was due to the internal debate of epistemological order, that is, by the review of disciplinary procedures such as the classification of materials, also by the pressure exerted by the laws of patrimony that exhorted to make archaeological management plans in the colonial buildings that were remodeled

within the intervention policies framework of historical centers.

At the beginning of the 2000s, the practice of historical archaeology was consolidated through the appearance of catalogues of colonial ceramics such as the one published by the Banco de la República in 2002 (Therrien et al. 2002), made to facilitate the identification of colonial materials in the Altiplano Cundiboyacense (high plateau) and the Colombian Caribbean. It is interesting to note that this exercise in the generation of catalogues has not occurred with pre-Hispanic ceramics, perhaps for one reason: the colonial and republican artifacts that began to be imported came from factories that were already standardizing production processes. This did not happen with the pre-Hispanic ceramics that were not elaborated following the rigor of the exact replica, since to a certain extent each object was unique.

Within this historical archaeology boom in Colombia, which occurs between the 1990s and 2000s, the contribution of Colombian researchers to understanding the complexities of the colony is clear and evident. The colonial process, as indicated by the archaeological record analyzed, was not a process of population replacement but, on the contrary, involved negotiation processes that occurred within the framework of the native populations' subordination to the colonial regime. In addition to this conclusion, which seems more a statement of a programmatic agenda, another great conclusion that can be drawn is that historical archaeology, in Colombia, emerged without clear connections with the processes of historical research that had been speaking of the indigenous situation since the ethnohistorical data. In this sense, historical archaeology in Colombia can be understood more as an accident, as the result of a demand, rather than as an agenda that tried to solve key problems such as the processes of miscegenation and the configuration of republican societies. As inferred from a premise put forward by the Colombian archaeologist Carlo Piazzini (2011), in the Colombian academy, the separation between history and prehistory, based on the separation between the written word and orality, made archaeology concentrate on the agraphical past of indigenous societies and history on the written language periods. According to Piazzini, this has meant that archaeology does not turn its eyes to spatialities, others, to the landscapes of alterity, which were named by Michel Foucault as heterotopies (Foucault and Miskowiec 1986).

The end of the 2000s and the beginning of the 2010s mark a rupture with the academic agenda that was set in the 1990s. The implementation of a neoliberal agenda in South America increased investment in infrastructure in such a way that large infrastructure projects arose that demanded preventive archaeology programs (Gnecco and Dias 2017). This has made the practice of archaeology no longer an academic project and, in this critical sense, has become an instrument of capital. Although this seems to be a minor detail, the data produced about the colonial periods are done on demand due to the obligation to form teams that would prevent any type of damage to the archaeological record mainly at the time when real estate assets are intervened. This pressure has led the State to demand preventive archaeology studies in works that affect areas such as seabeds; in this way the pressure for regulatory compliance has made archaeologists in Colombia specialize in registration techniques of underwater archaeology, without using or thinking underwater archaeology to expand the spectrum of possibilities to understand the past. When looking at what Colombian archaeologists write about submerged sites (García and Cairo 2003), there is a clear tendency toward technical and conservation procedures, but little is said about how the submerged record, in this colonial case, could help to understand the dynamics of the conquest and the colony from the point of view of archaeology.

Current Debates

In 2014, the Colombian philosopher Santiago Castro-Gómez published a historical work that investigated the processes of conformation of colonial society in the former Viceroyalty of New Granada, whose capital was the current Bogotá, capital

of Colombia (Castro-Gómez 2004). In that investigation, it was clear that the conformation of the Creole identity had to occur in a double process that united two things or two problems. The first problem was the problem of identity, which was addressed in the academy, in politics, and in religion, and that was resolved by pointing out that America was a new extension of the known world, especially by the people and societies responsible for making explorations from the Mediterranean to the West. The sailors, of course, did not travel alone, and the planning of the routes and the financing were related to the closeness to powerful families, and the proximity of these families to the clergy determined the success of the investments on many levels. It has been well documented how the continental exploration implied an imaginary that allowed the conquest through its ideologies and practices; in this sense the ideological projection of a Western Europe in America, supposed that it was catalogued as new but not unknown. In fact, it was an ancient world too that was not prepared to respond to unknown forces.

As America is a replica of Europe, but new, with the positive and negative things that can be recognized from this adjudication, it was necessary to solve the problem of coexistence with the others, with the existing native populations; that is the second problem. Castro-Gómez explains it clearly: the native populations were analyzed in a system in which these communities remained as the antipode of civilization that, understood as a concept, was that set of principles that allowed defining and justifying the ideological framework of colonial society, and likewise to every identity component, there is an opposite part. In that sense, the segregation of indigenous and Afro-descendant communities in the education systems was justified, so as to mention an example. This generated a characteristic feature of Colombian and Latin American society: the socioeconomic differentiation is equivalent to racial differentiation.

As identity is defined, and as policies of segregation and domination are generated, the spatialities and materialities that gave meaning to social differentiations were shaped. The import of buttons, glasses, jugs, fabrics, lace, wood, and spices supposed a consumption of artifacts that allowed pointing out the differences with the lower classes that in general were indigenous or peasant. However, this segregation never implied the abandonment of indigenous and peasant artifacts and cooking that were considered as regional identity markers (Londoño 2011).

As it can be seen from Castro-Gómez's work, it is clear that the colonial discourse built a negative image of the indigenous that served to exclude indigenous communities from the colonial educational system; under this equation the usurpation of land and the payment of taxes were acts justified as a necessity, and in exchange the colonial state and its agents ensured the indigenous people's evangelization.

Something that must be clarified here is that these forces, these contradictions, these intersections, which allowed the configuration of not only artifacts but also spaces, cities, connections, and infinity of elements susceptible to be analyzed by archaeology.

Walter Mignolo (2016) has described with great clarity how that construction of the other caused the denial of indigenous communities' ontologies and how, through an ideological system in which alterity justified colonization, the colonial society was moving toward the consolidation of a Creole identity. Mignolo explains that Creole identity finally led to what this author calls "the colonial wound." In his opinion, this phenomenon occurs because of the double negation that occurs within the set of ideas that give meaning to the Creole identity. At a first level, the fact that America is not Europe is denied (and the argument that the difference with Europe is simply geographical is configured); on another level, contemporaneity with indigenous communities is denied (and the argument that supposes indigenous communities as things of the past is configured). In addition to this idea and related to the "colonial wound," Mignolo explains that there is another phenomenon: coloniality, understood as the ideology that subordinates others, that is, at the same time that one depends on the other, and the other is needed, the other is invisibilized, oppressed, and exploited. One of the advantages of the concept of coloniality is that it allows us to understand that the subordination and coexistence had generated the colonial landscapes,

understanding with that all the spatiality and materiality that made visible and available the social differences theorized in philosophical, political, academic, and religious discourse.

Although this panorama presented by cultural studies is detailed and opens ways to understand the forms of submission, the emphasis on texts, said by the academic of the colony, what is said in the colonial document, prevents seeing those spaces, those intersections where it is possible to see the crossing, and the detours, the unpredictable situations that are constitutive of a colonial identity in Latin America and the Caribbean (Trouillot 1992). Although it seems unprecedented, some archaeologists have begun to discuss these issues pointing out, from the archaeological record, the limitations of the generalizations that are made from areas such as cultural studies (Londoño 2010). While it is true that from the legal point of view there was segregation, a gentrification, there were areas crossing spaces where other forms of *mestizo* identity were formed that it would be absurd to strictly link to Creole identity models. Colombian sociologist Edgar Rey Sinning has shown (Rey 2000) that the carnival, in the Colombian Caribbean, is the ideological set that expresses, par excellence, the regional values. The carnival, according to his extensive research, which has its roots in the colony, is a *mestizo* expression displayed through allegories and ironies made up of characters that can be distinguished from the colonial amalgam as Spaniards, Indigenous, and Afros. Rey Sinning's work make it possible for historical archaeology to consider analysis pathways such as carnival archaeology, since in these populations there are elements of colonial material culture that are still used by the communities. In this way, it would be possible to evaluate cultural continuities of several centuries combining archaeology, history, and ethnography and showing how the processes of identity construction took other paths in these regions.

Due to this debate, some anthropologists have made significant contributions in the understanding of these heterotopic zones, to use the expression popularized by Foucault (Foucault and Miskowiec 1986). In the case of the city of Popayán, as it was said before, a colonial city of southwestern Colombia, anthropologist Hernán Torres (1999) described how the rituals of Holy Week, which are very popular in the southern Andean region of Colombia, are reversal rites that exalt, only once in the year, the role of the others who usually were and are part of wealthy families' serving staff. Hernán Torres's work complemented North American anthropologist Andrew Hunter Whiteford's observations (Whiteford 1963). In his ethnography of Popayán, he described how in the city center, in families of upper middle class, the residence of the serving staff was on the ground floors, which in the end meant a coexistence of racialized social classes where, despite coexistence, the wealthy classes segregated indigenous and peasants from political and economic, but not cultural spaces.

This strange interaction undoubtedly explains that it is in the Popayán region where one of the most solid indigenous movements in northern South America persists. It would be very risky to say that this relationship is positive or that it shows forms of equality and balance. Under no circumstances, this interaction occurs in the face of a process of territorial dispute in which some indigenous communities have obtained their land's restitution that were inappropriately seized during the colony and the republic.

This cartography of the history of the interactions that take place within the framework of the Creole society could be considered one of the most important debates that have been established in the historical archaeology practiced in Colombia. In this debate, it is clear that archaeology, as a discipline that studies material culture and the archaeological record, can facilitate the understanding of subtle forms of human interaction within the dynamics of colonial regimes that indicate interstices that allow understanding the ideological framework. What is deeply underlined in this argument is the idea that archaeology, with its methods and theories, can help understand how space and material culture are elements of a wider network that allows human beings to perceive the world in certain ways; obviously, this perception is not a consequence of a given reality but the result of an interaction with materialities and spatialities that allow us to experience the differences

as real. In this way, the material world is possible because of the ideological dimensions that give horizons of meaning to societies, and these horizons of meaning are possible because of the materialities that underlie them and give them dimension and depth.

In some senses, Mark Leone (1995) had already suggested something similar by arguing that anthropology, archaeology, and history, by focusing on the understanding of the conformation of capitalism, would probably erase their disciplinary boundaries given the fact that the world capitalism is not only shaped by ideologies but is shaped by ideologies that have spaces, shapes, and dimensions, which are given by materialities and spatialities.

As it can be seen from what has been said here, historical archaeology in Colombia is still a recent practice that is not, up to the present (2018), three decades old. The contributions of the archaeologists who have crossed these paths are relatively few, circumscribed to specific cases and without debates that enable a reflection where it would be possible to develop conceptual or political innovations.

Colonial Encounters, Archaeology of

Alistair Paterson
School of Social Sciences, University of Western Australia, Perth, WA, Australia

Introduction

This chapter provides an overview of the archaeology of colonial encounters. From the perspective of considering archaeological approaches to date, the vast majority of studies considered in this review highlight encounters between various European-descent societies and non-European indigenous "others." Here definitions of colonial contexts from the perspective of archaeology are considered initially. Key locations around the globe are described in terms of the form of encounters, the state of archaeological work, and the key studies. This contribution reviews the various explanatory approaches in archaeology and concludes with a consideration of the significant opportunities for archaeology to inform on the numerous one-on-one individual cross-cultural encounters and interactions within colonial settings that increasingly defined the last millennium of human history.

Definition and Historical Background

Colonialism has meant various things to archaeologists over time. Colonialism has characterized (1) places where the abrupt arrival of Europeans suggests a clear fault line in the historical sequence, (2) other locations where colonial relationships have longer and thus more complicated histories, (3) and historical settings that did not involve Europeans but other cultures in forms of colonial relationships.

1. When we consider the modern world, we think in global terms. Everywhere is somehow connected to elsewhere. Our economies are

enmeshed in global systems of finance, objects and resources move around the planet, and the diffusion of domesticated plant and animal species has blurred the biological regionalism and comparative isolation that characterized the world of our earlier ancestors. Even the human species itself has – in many places – shifted to a more "global" animal, where long-separated ethnicities have shared their pathogens, DNA, and cultural practices. The global nature of the modern world is a subject of inquiry for many disciplines from economics to anthropology. Archaeologists have studied the multiple individual examples of how this world came about – some through local/regional studies such as the arrival of, say, European societies in various locations around the world (as explored below). Others have conducted ambitious comparative studies of colonialism. For example, historical archaeologist Charles Orser compared colonialism in Ireland, Brazil, and North America in attempt to define a "historical archaeology of the modern world" (Orser 1996). Comparative studies of colonial contexts follow in a comparative tradition in archaeology, as used to understand other periods of human change such as the shift toward farming, urban life, and forms of social complexity.

Whatever the scale, for many archaeologists, the arrival of migrant colonists in a new region is a convenient definition of colonialism. The study of colonization has in the past been sometimes largely uninterested in the forms of cultural encounters that characterized these contexts. However, this has changed over time, as seen by the way in which James Deetz's early definition of historical archaeology as "the archaeology of the spread of European cultures throughout the world from the fifteenth century" was amended by him to add: "and their impact on and interaction with the cultures of indigenous peoples" (Deetz 1977: 5). The study of arrival of Europeans saw the development of the subdiscipline of historical archaeology, first in North America, then Australasia, and elsewhere. In Europe the fields of medieval, postmedieval, and industrial archaeology covered aspects of this time period. As such, the study of encounters in colonial settings by archaeologists occurs within and beyond the field of historical archaeology. In fact, the focus of historical archaeologists on time periods for which documentary evidence existed limited their ability to appropriately analyze those "people without history" (see Deagan 1988; Lightfoot 1995; Colley and Bickford 1996).

Outside of the Old World core, the tempo of colonization episodes by European societies increased dramatically across the second millennium CE. Some key *early* events include the colonization of the northern Atlantic islands by the Norse, arriving in North America by 1000 CE; the later discovery by various fishing experts, such as the Basque, of fish-rich waters off the North American Atlantic seaboard; the colonization of the western (Azores, Madeira, Canary, Cape Verde islands from the 1300s) and then the eastern Atlantic (beginning with the Caribbean archipelago in 1492 and followed by Mexico and South and North America); the exploration and colonization of Africa (key dates being the Portuguese capture of Cueta, Morocco, in 1415, then the successful navigation of the tip of Southern Africa by Vasco da Gama in 1498); the arrival of European merchants in East and South Asia following Vasco da Gama's entry into the Indian Ocean in direct competition to prevailing Islamic, African, and Asian trade systems; and the exploration of the Pacific and Australasia. These events were driven by different agendas; however, common to many was the demand for better access to known resources – notably the Asian goods moving through the "Spice Roads" arriving in Medieval Europe through intermediaries. This required the establishment of colonial outposts at key nodes to control and provision trade. In time some successful nodes grew from merchant outposts to more extensive forms of colonialism – such as seen in India, West Africa, Southern Africa, and Indonesia. In

other locations, such as China, coastal outposts never successfully translated into more extensive permanent forms of colonialism at the level of the state. The discovery of new resources, such as the South American silver or Caribbean islands suited for plantations, also fueled colonial projects. Other colonies existed for geopolitical ambitions or to remove unwanted populace (as in the case of penal colonies such as Australia and Bermuda). Whatever the reason for their existence, colonies inevitably invoked competition with existing indigenous populations.

Key work detailing these events at a global level includes Immanuel Wallerstein's work in the Annales School on world systems particularly *The Modern World-System* volumes (e.g., Wallerstein 1974), Eric Wolf's (1982) *Europe and the People Without History*, Phillip Curtin's (1984) *Cross-Cultural Trade in World History*, and Alfred Crosby's (2003) *The Columbian Exchange: Biological and Cultural Consequences of 1492*. For archaeologists and historians, these studies track their intellectual efforts back to earlier work in the historical sciences such as Gordon Childe's (1943) *What Happened in History.*

Necessarily, the arrival of European outsiders and their entourage (such as African slaves in the Americas) marked a distinct change. One culture's "colonization" was often another's "invasion," especially where a form of "conquest" was required. In locations where there was no indigenous written tradition, colonization has been perceived as the beginning of the "historic" period, before which there was a "prehistoric" period. Additionally, in North America the idea of a "protohistoric" period was popularly conceived, describing the period after the arrival of Europeans in 1492 before any local expression of permanent colonization (Rogers and Wilson 1993). More recently the concept of "historical" and "prehistoric" periods has been critiqued in some countries – such as Australia – as privileging European societies and their literate traditions over others (Deagan 1988; Lightfoot 1995; Colley and Bickford 1996; McNiven and Russell 2005). Put simply, prehistory is felt to imply "without history" rather than "before written sources." In many nonliterate societies, oral traditions maintained deep histories as counterpoints to European dominant histories. Kent Lightfoot argues that "the current separation of prehistoric and historical archaeology detracts greatly from the study of long-term culture change, especially in multiethnic contexts" (1995: 200).

Historically, narratives of colonial encounters have focused on the perceived abrupt shock that marked the arrival of outsiders in indigenous worlds. Sometimes initial encounters may have been truly unexpected. For the Maori of New Zealand, for example, new categories to describe outsiders (*pakeha*) and indeed themselves (Maori) were required. In only rare instances were societies truly isolated from others, for example, the Tasmanians' isolation from Australia had lasted at least 8,000 years following the creation of Bass Strait by rising seas. Most societies, however, were aware of the presence of new colonists in advance of their arrival as information circulated through social networks. For example, in Arnhem Land in the Northern Territory, Aboriginal people had been informed of the arrival of Europeans in island Southeast Asia during their seasonal encounters with Asian fishermen who maintained camps across the northern Australian coast. Thus, when the British arrived in (for them) remote and isolated Arnhem Land, they were recognizable as "Balanda" (from "Hollander"), an ethnic category acquired through preexisting cross-cultural encounters (Paterson 2011). Today white Australians in Arnhem Land are still called Balanda. In another example, in the Great Plains of North America, for over a century in advance of the direct presence of European colonists, Native American societies underwent dramatic changes that resulted from the introduction of horses and their ability to trade for guns.

2. The concept of modern or recent colonialism as discussed above is specific to the last millennium and the foundation of the so-called

settler societies (such as the USA, Australia, Canada, New Zealand, and Argentina), in which the indigenous population is eventually outnumbered by the migrant-descent population. Thinking more broadly, others have demonstrated how more ancient forms of colonial relationships existed. The various colonial enterprises of the Greeks, Romans, Phoenicians, and other ancient states are well known (Lyons and Papadopoulos 2002). Christopher Gosden (2004) in *Archaeology and Colonialism: Cultural Contact from 5000 B.C. to the Present* takes a 7,000-year perspective on forms of colonialism – as defined by the establishment of colonies outside of one's own country and the various differential power relationships that may arise – beginning with ancient Mesopotamian city states of Uruk and the Aztecs in Mesoamerica. His approach highlights the important ways that material culture can reflect ancient power relationships that resemble colonialism. Importantly these too required forms of cross-cultural encounter and entanglement and were not confined to the involvement of Europeans.

3. When considering the fulcrum of Europe, Africa, and Asia over the length of time adopted by Gosden, the idea of relatively abrupt and bicultural encounters, such as that implied in James Deetz's definition (above) of historical archaeology, is replaced by a broader recognition of "encounter" within colonial realms and one not requiring the presence of Europeans. While these have to date been less the focus of archaeological attention, one imagines that future work will explore these places and histories in detail. In Asia, the history of state societies and their influence over others through trade, religion, and warfare has often been the privilege of historians over archaeologists, at least for the various literate Asian states – in the Americas and for sub-Saharan Africa, the reverse has been true. Whether these always result in "colonial" relationships depends on ones' definition of colonialism – which ranges from Gosden's wide definition to a specific focus on modern (last 500 years) instances. What is clear is that a European-defined approach is restricted. To take an example, when the Portuguese finally entered the Indian Ocean in the late 1400s, it marked the end of over 2,000 years during which Europe was only able to access commodities from Asia (such as spices) through middlemen – via the ancient Silk Roads (one route across Central Asia, the other by sea). Islamic trade networks dominated the Indian Ocean, although other powers had been critical. The Chinese experiments with maritime colonial enterprises in the Indian Ocean at least had already ended by this time, as Admiral Zheng He's fleet had explored South Asia and East Africa in the early 1400s.

What is clear from the three characterizations of colonial contexts is that it is almost impossible to consider colonial contexts without taking into account culture contact. Stephen Silliman (2005) argues this effectively in his exploration of the usages of "culture contact" and "colonialism" in North American archaeology. The core issues are of power and the way power structures' relationships between different peoples in colonial circumstances. A key characteristic of colonial domains is the unequal relationship that underpinned dominant colonial actors over less powerful indigenous people. The provision of cheap food, labor, and knowledge by indigenous peoples made many colonial societies sustainable and economically rewarding for colonial powers. In materialist thinking, objects and built places (including the organization of colonial landscapes) provide direct evidence for colonial-era behaviors, not just of colonists but potentially of indigenous peoples too, and the ways that they interpreted, accepted, and resisted colonial behaviors.

Key Issues/Current Debates

Approaches to Encounters

A recent global review of the study of cross-cultural encounters globally over the last 1,000 years in the various regions reveals different archaeological concerns (Paterson 2011).

Regardless, the study of colonial encounters wherever these occurred is essentially a study of *culture contact*. Historically, the term described the moments of "first contact"; however, increasingly within archaeological practice, the study of culture contact focuses on the processes of cultural entanglement following colonization and within colonial settings. Several distinctly different colonial settings have been defined and include, as illustrated by historian Phillip Curtin, (1) merchant diasporas, (2) territorial empires, (3) settlement empires, and (4) plantation complexes (Curtin 1984). Curtin was interested in the economic aspect of trade-driven European settlement. Each of the four types required different forms of colonization, settlement history, and use of power and capital – but all involved cross-cultural contact and various forms of unequal access to indigenous labor and land. The results have been described by archaeologists as requiring diffusion, invasion and conquest, contact and exchange, acculturation, and genocide.

Cultures in contact invoke change on each other – this is termed *acculturation*. This understanding is ancient: Plato argued in 348 BCE that contact should be minimized as the "intercourse of cities with one another is apt to create a confusion of manners." The potential influence of foreigners concerned states, for example, the rulers of Japan and China when encountering Europeans along their coasts and waterways sought to keep them restricted to state-controlled ports, such as Canton. Not all societies were successful in their efforts, as demonstrated by Moctezuma's failure to control the destabilizing efforts of the Spanish conquistadors who allied with other Mesoamericans, which caused the collapse of the Aztec state in 1521. For non-state-level societies around the world, the ability to repel new colonists was inevitably doomed. Technology often played a critical role – in many settings European colonists tended to have superior military technology fueled by infantry with munitions, although older practices such as mounted cavalry underpinned Spanish warfare in the Americas against unmounted street fighters.

Another key element heralded by the arrival of colonists was demographic change. Various scholars have explored the scale of disease and resulting mortality that arose from the movement of pathogens around the world following the various European diasporas (Paterson 2011). Crosby (2003) described this as "The Columbian Exchange," although it also applied in various settings around the world and not just in the Americas. Certain diseases were particularly catastrophic, such as smallpox. There are debates about the size of indigenous populations prior to contact, something which archaeology attempts to address by studying past settlements. As diseases moved in advance of Europeans, the usefulness of historical accounts to determine precontact demography is often questionable. In many settings, significant demographic decline at first contact through disease and war is evident. Other contact-era processes acted upon societies, particularly in Africa where the demand for slaves for Islamic markets and then increasingly for the trans-Atlantic slave trade saw intercommunity warfare and population decline in areas well beyond the presence of colonial powers. Such dramatic processes probably fueled racist ideas of "fatal impact" whereby native peoples would inevitably decline following contact with superior whites and others.

There have been various theoretical models used to explain culture contact, with many key developments occurring in North American anthropology. The idea of acculturation has the longest pedigree, becoming popular in the nineteenth century. In the 1880s J. W. Powell, working for the Bureau of American Ethnology, used acculturation to describe psychological changes experienced during cross-cultural imitation, followed by colleague W. J. McGee, who like many of his time thought in social evolutionary terms and thus saw culture contact as a means for savage or barbaric societies to become civilized and enlightened. Such concepts underpinned many colonial endeavors of this era. In the 1930s acculturation was increasingly used as a tool to measure cultural change and thus became essential to social scientists in

North America. In 1936 "A Memorandum for the Study of Acculturation" was published in *American Antiquity* (Redfield et al. 1936). While the definition described how change could occur to both cultures in contact, in reality the focus of most researchers was on Native American responses and not forms of European acculturation. Edward Spicer, working in Mexico and the Southwest, defined types of acculturation including incorporation, assimilation, fusion, and compartmentalization (Spicer 1961). He was interested in why certain societies maintained their cultural practices and compared these to Basque, Irish, and Welsh reactions to past oppressors. Acculturation theory tended to focus on "donor" and "recipient" groups whereby change tended to be experienced by the weaker recipients. The use of such approaches was based on the assumption that archaeologists could use changes in material culture as a proxy for social change. However, the potential nuances of how material culture may be used in colonial contexts were largely absent from these discussions.

By the 1970s, new explanatory models were being proposed to explain forms of cultural engagement. In North America, the five-hundredth anniversary of Columbus's voyage of 1492 inspired new research into the topic, as seen in the three *Columbian Consequences* volumes (edited by David Hurst Thomas [e.g., Thomas 1989]). The new thinking stressed that "Culture [is] change. . .neither one-sided nor solely governed by European intentions and strategies. Rather it is evident. . ..that [indigenous peoples'] attitudes and actions. . .played a large part in determining the impact of contact" (Wilson and Rogers 1993: 3). To take one example, in the 1680s, Pueblo people of New Mexico revolted against the colonial Spaniards, successfully repelling them. Colonial settlements were abandoned, churches destroyed, and in the archaeological record people abandoned the once ubiquitous pre-Hispanic "Jemez Black-on-white" decorated ceramics as it had become associated with the Spanish, with Franciscan missionaries producing objects like candlesticks. The ware no longer just represented indigenous material practices, but also Spanish dominance (Liebmann 2008). A simple acculturation index would fail to detect the nuances of resistance and innovation and the shifting meanings of material culture in contested colonial settings.

As a result, various useful models exist, including theories related to acculturation and assimilation, resistance and dominance, forms of cultural accommodation, hybridity, subaltern practices, and agency. Others return to existing models, for example, exploring whether optimal foraging theory is useful for explaining how indigenous people dealt with new resources in colonial landscapes (Birmingham 2000). Another aspect of explanation concerns how instances relate to wider processes, notably frontier theory and core and periphery models. In colonial settings this is important as both, in part, explore how colonial centers related to colonial worlds.

In colonial settings, then, cultures have been long seen to be in flux. Conservatism, innovation, and creation are critical aspects of daily life for both colonists and various indigenous others. Sometimes concepts of "indigenous" become more blurred, as new forms of society developed. Key concepts such as ethnogenesis and creolization are used by archaeologists to document new forms of cultural practice that arose from the mixing pot of colonialism. A key archaeological proponent of creolization has been historical archaeologist Kathleen Deagan whose work has explored Spanish and American colonial communities in both Florida and the Caribbean archipelago (Deagan 1988; also Paterson 2011 for detail).

Future Directions

Long-Term Studies of Colonial Complexity

Some more successful archaeological studies have taken on the challenging potential of archaeological analyses and seen shifts from simple two-way cross-cultural processes to more complex explanatory models.

Colonial settings were not just simple binary contexts, but constituted of more complex

relationships. Kent Lightfoot heralded a shift toward models that highlighted the complexity of ethnic interactions in colonial settings – his study (Lightfoot 1995) of the various ethnic communities at the early nineteenth-century Russian Fort Ross in northern California was described as pluralistic and marked a shift from an indigenous/colonizer paradigm to a more subtle focus on the material record of shifting ethnic behavior in a colonial outpost located in traditional lands of the Kashaya Pomo.

Archaeology provides a long-term approach within which to locate the colonial period. In the study of Guale life at St. Catherines Island off Georgia, which in the 1570s became a Spanish outpost of the La Florida colony, the American Museum of Natural History has documented 5,000 years of indigenous lifeways. Through a long-term approach, the ways in which the colonial period was reflected in indigenous practices were measured in the archaeological record, as indicated in chiefly power structures, gendered behavior, use of material culture, settlement patterns, health and mortality, work, trade networks, burial, and religiosity.

Colonial "frontiers" suggest to us regions that existed well beyond the formal presence of Europeans where however the impacts of change were still felt. This is perhaps best understood in Africa, where for centuries foreign outposts (such as in West Africa) and coastal communities (such as the medieval Swahili states in East Africa) had far reaching impacts on the interior of the continent through demand for traded commodities and slaves. In West Africa, the work of Ann Stahl in west central Ghana of the Banda is similar to that described for St. Catherines Island, by situating processes of cultural entanglement in a longer time frame. Banda sites were well inland from European-African encounters along the coast, yet in this chieftaincy during the seventeenth and eighteenth centuries, preexisting power structures long associated with Saharan and Sudanic trade networks were disrupted by the shift toward Atlantic slave trading. In this "colonial frontier zone," the African Asante became dominant; then in the 1870s, British colonization occurred. Stahl's excavations reveal the continuities and shifts in communities and their practices over these centuries of change at the shifting edges of the colonial world.

The Materiality of Colonial Encounters

The archaeological study of colonial settings uses material evidence in addition to evidence from environmental and landscape records, historical sources, oral histories, and pictorial sources. The focus on material evidence poses serious challenges and opportunities. In colonial settings, the archaeological concept that objects and the way that they were used are equated with social identity is less solid. Instead, objects appear to shift in meaning depending on the user. The work of Nicholas Thomas (1991) highlights that in colonial contexts objects were used by colonized people to reject, embrace, and manipulate the intentions of colonizers. This suggests that simple material measures may miss nuances of the colonial world and indigenous processes of conservatism, experimentation, change, and even ethnogenesis where entirely new societies arise from colonial-era dynamics (i.e., the Metis in Canada).

Politics of the Past

The withdrawal of colonial powers in the twentieth century provides another set of historical "fault lines" that continue to reflect processes of cultural entanglement. Postcolonial settings have developed a set of political actions, literature, and theory. In archaeology, material culture has been used in novel ways to explore postcolonial historical cross-cultural processes, such as in Africa where the postcolonial settings are numerous and present legacies of direct relevance to Africans today (see Reid and Lane 2004 for African studies). The descendants of colonialism often claim rights to traditional lands (such as in Australia and North America), practices (such as hunting or social and religious practices), and material and ancestral remains held in colonial-era collections and for the right to actively participate and regulate the investigations of their past. These are shifting archaeological practice and the ethics of exploring the past in the present,

be it postcolonial or not, and are likely to be key threads of future research on colonial encounters in "historical archaeology."

Colonial Expansion and Nation-State Building: Influences on Archaeology

Carl Henrik Langebaek
Department of Anthropology, Universidad de los Andes, Bogotá, Colombia

Introduction

After World War II, when European powers lost control over large areas of Africa and Asia, ownership of the past became a key, explicitly relevant issue, and new nations were created. Precolonial history became often used to justify resistance against domination and even as the basis for constructing new nations. Even as the study of the past enjoyed the status of a clearly legitimate "science," for some in ways comparable to the natural sciences, who owned the past, how it is used to justify colonialism as well as nationalist movements, and how it works to justify conquests – or "wars of liberation" – became legitimate objects of interest for many archaeologists and historians. The times when the study of the past was considered as being free from the social context are completely over. Texts on the history of disciplines like history and anthropology, including some introductory textbooks, refer to the debate and include a rich biography on the subject.

The imperial crises in the first decades of the twentieth century caused these concerns to thrive. In the 1920s and 1930s, some of the most obvious ways that the past had been manipulated in the name of political movements and totalitarian ideologies became clear. The obsession with the past and racialized history in National Socialist Germany, Italian fascists' fondness for the glories of the Roman Empire, as well as ideas about Italian's right to govern Africa, and even the Soviet policy of erasing any evidence of non-Slavic history in Russia or Eastern Europe are all examples of how the past was not neutral. Furthermore, the consequences of manipulation that led to the inhalation of millions of people in Europe became evident.

However, the weakening of the European empires after the war made it clear that these extreme cases are part of a long tradition of using the past for political means, which was used to justify the creation of empires throughout the nineteenth century. Several people had, at this time, questioned the relationship between archaeology and power relations, but perhaps, for many, it was history, in charge of creating broader narratives, that had been manipulated to produce images about the past that were clearly distorted by imperial and colonial perspectives. Conversely, archaeology, which focused on studying objects and curiosities, was perceived as less involved in these processes (Díaz-Andreu 2007). Today, it is clear that archaeology is not a value-free or neutral science and that its relation to the politics of domination is not limited to the extreme cases that were so evident after the war. The political manipulation that archaeology can offer, and that it certainly has offered throughout history, is only one way in which power has manipulated the past. Any political project that encounters evidence from the past needs to confront it: either by including it and pursuing its own interests or by ignoring it and pursuing its own interests.

Historical Background

Ever since the 1980s and 1990s, particularly in Europe but also in the United States, a deep discontent began with a decontextualized disciplinary practice that did not take into consideration society, economics, and politics. The history of archaeology, which is well-known through texts such as Glyn Daniel's (Daniel 1981; Daniel and Renfrew 1988), was strongly criticized for offering only an "internalist" discourse of the practice. They reduced archaeological developments to an inner evolution of increasingly accurate and definite scientific knowledge about the past, completely ignoring the context in which such knowledge was produced (Moro-Abadía 2006). Instead, a great deal of effort was focused on trying to understand how external factors explained how archaeology was practiced as

well as the complex interplay between accounts of the past and social contexts (Trigger 1980, 1989; Schnapp 1993).

Postcolonial studies began to develop during the 1980s and 1990s. This was part of a wider context within which archaeology began to ask itself about the way that it had understood social relations, gender, and key issues such as race and nationalism. A large part of the studies specifically concentrated on the relationship between archaeology and nationalism (Díaz-Andreu and Champion 1996 Kohl and Fawcett 1995; Alexandri 2002) and on gaining a better understanding of the colonial processes themselves (Lyons and Papadopoulos 2002; Dietler 2010). Other studies focused on how archaeology related to colonial processes (Evans and Meggers 1973; Bray and Glover 1987; Sheppard 1990), and some took inspiration from Said's (2002) *Orientalism*, which exposed how imperialism as a discourse makes statements about colonized regions and then expresses authoritative views on them (Bernal 1994; Schlanger 2002; Shaw 1990). Efforts were also made to understand how colonial discourse confirmed that the backwardness in colonized regions was deeply rooted in the past and even how colonial powers presented themselves as the guardians of local traditions (Díaz-Andreu 2007: 210) and how colonial discourses interacted with local interests and politics, which led to hybridity (Bhabha 1994). Other studies focused on the general social structure of the colonizing and colonized society, including gender relations (Gero 1985).

Not only were postcolonial studies diverse in scope, they were also varied in terms of their intellectual background. They were influenced by the likes of Gramsci, Foucault, Said, and Bhabha, and as Moro-Abadía (2006) notes, they used a set of terms such as "colonialism," "imperialism," "neocolonialism," and "globalization," with a limited time scale that can be contrasted with their broad aims in terms of social critique. In political terms, postcolonial studies aimed at nurturing a political project that challenged colonial domination and exposed the legacies of colonialism. Its range of study was generally limited to the time when archaeology emerged as a science, which was more or less the time of the European imperial expansion in the latter half of the nineteenth century. To a certain extent, its emphasis has been limited to the development of the important evolutionary discourses that are based on the works of authors such as Lubbock and Morgan who, for many, positioned European societies at the apex of humanity and nurtured the idea that the history of the Old World subsumed the history of all civilization. Studies have focused on this model of "civilization," which archaeology helped to create, and the rest of the world could be understood using these parameters (Lydon and Rizvi 2010).

There are, indeed, some points at which the postcolonial vision is incomplete: the critique of asymmetric relations of power and, specifically, of colonialism came far earlier than postcolonial critique. Marx and Engels, for example, envisaged a critique that was based on not only an economic perspective but also a political and ideological one. Postcolonial studies have often focused on the ideological: the creation of new identities, hybridity, agency, and consumption. They have often forgotten parallels in the material world: the asymmetry of powers, wars, impoverishment, and disease (Lydon and Rizvi 2010). Another problem is that their critique focuses on what is identified as the innate values of Western colonial expansion and domination (Gosden 2004). To provide examples, most studies do not take into consideration forms of expansion that have characterized Islam (Alexander 2001) or those that have worked internally in Latin American countries that have justified systems that exclude socially but are hostile to evolutionism (Langebaek 2009).

Similarly, these studies do not usually provide a long-term perspective of the complex relationship between power and the view of the past or of the bids for power and local expansionist projects. Its critique has been more useful to demystify the idea of a neutral science than to unravel the relationships between scientific ideas, dominant ideologies, and asymmetric power bases: including the bases of exploitation, on a broader historical and cultural scale. The chronological scope is, indeed, very limited as postcolonial studies frequently limited analysis to the last 100 or

150 years at most. Although there was a legitimate basis for this, since they wanted to focus on phenomena specifically related to the European expansion and its subsequent decline at the end of the twentieth century, the truth is that much of the complexity regarding the relations of domination had biases in terms of the Anglosphere and, to a lesser extent, to the Francosphere. The Spanish and German spheres have not been as extensively researched, not to mention the relations of power issue and the expansion of non-European empires that are also legitimate spaces for reflection and critique. To some extent colonial studies are, paradoxically, Eurocentric.

The History of the Past: Archaeology's Past

Political domination and ownership of the past have run together long before European expansion. Old States, both in the Old World and the New World, had to contend with the monuments that they themselves had destroyed or that were symbols of other powers existing and prospering in ancient times (Gosden 2004). State powers based on the premise that ruling lineages were eternal and that centered their powers on old traditions tried, conveniently for them, to include the history of the regions that they dominated claiming, for example, a historical continuity that was doubtful at best. An example is the Mongolian Yuan dynasty in China, which incorporated some local traditions, including Confucianism; another is the successive powers in central Mexico after the fall of Teotihuacan that persistently claimed to be the successors of the governing lineages of this city-state. The so-called pre--Columbian Andean emperors are also important: each of them claimed to have roots in the States that proceeded them.

In another context that predates the relatively recent European expansion, the profound narratives that are characteristic of the monotheistic religions, especially Christianity and Islam, are also based on arguments that support the consolidation of power and a keen alignment with the past. Christianity and Islam, initially reactions against the great powers, ended up fueling political expansion and considering the past of the societies under their realm as impure in terms of their respective beliefs and basis for political authority. Both ordered history linearly, with one single narrative that has a series of unquestionable landmarks and a supposed universal value. The structured a "past" and a "future" in terms of the negation of the validity of other beliefs. The concept of unbelievers who need to be converted to the "true" faith provided, and still provides in some contexts, important tools for the expansion and domination by earthly powers, especially when they claim to have a special relationship with prophets such as Jesus or Mohammed. The expansion of European Christian powers at the expense of the infidels from the north of Europe and the enslavement of Africans by Arab powers in Africa are the expressions of expansionist ideologies that justify the conversion of infidels. Some of the most important empires after the year 1000 are monotheistic empires, for example, the ancient Persian empire or the sixteenth-century Spanish empire. In both cases, although they are supported by religion, they are not fully explained by it. The Atlantic States' power, particularly Spain and Portugal, was consolidated in the fifteenth century, and a type of expansion was strengthened that had never before been seen in which religion initially played an important role. It was, however, later replaced or complemented with other notions that better served imperialist objectives such as "civilization" and "race," which are ultimately more useful for more recent expressions of imperialism, specifically English as well as French (Stocking 1987).

Latin America is an interesting case as it sums up many of the relations between colonialism and manipulation of the past over centuries. As already stated, before the arrival of the Europeans, the ruling Aztec lineages – although recently arrived to Central Mexico from the north – traced their legitimacy back to old powers who had previously governed in the region. And they were not the first: throughout the centuries, successive powers in Mesoamerica appropriated the past of extinct societies. Teotihuacan was a source of inspiration for the Toltec and Aztec

societies in which the elites claimed to have links and ancestral relationships with the ancient founders of the biggest city that had been built before the arrival of the Spaniards. They also appropriated this past to differentiate themselves from the "barbarians" who were excluded from a long regional history. Moreover, ancient Mexican rulers proudly exhibited objects from afar that were obtained from exotic societies and claimed to have legitimacy and control over locals and foreigners due to a long history and sacred powers (Helms 1988).

The European invasion brought with it a new chapter in the appropriation of the past. With the Spanish conquest, notions of the past were developed that fulfilled their interests. A large part of this control was based on the expansionist principles of the monotheistic religions, in this case Christianity (Ricard 1986; Gruzinski 2012). The Indians were considered to be humans with a soul, thanks to the grace of God, but they did not know the word of God. One justification for the Spanish expansion was the task of turning the Indians over to the Crown and the Church. However, they found remains, such as hands or feet drawn in stone, that suggested they had previously been visited by Christian missionaries. This demonstrated their evil: they had known of the divine word but were determined to follow their own gods. In this way, the conquistadors, not infrequently, compared the Indians to the Jews of the Old World. Some of the Mexican monuments were important in the eyes of the conquistadors who helped to make Spain an empire capable of conquering glorious empires. As such, the Spaniards frequently considered the Mexican monuments to be comparable to Roman ruins and spoke of the glories of the places that were now under Spanish rule (Lupher 2006). Some conquistadors even developed the idea that the first inhabitants of the New World were the decedents of old inhabitants from the Iberian Peninsula, and thus the conquest was no more than a meeting of brothers.

The expansion of the Iberian empires began to decline throughout the eighteenth century, and it was replaced by other powers, notably France, England, and, to a lesser extent, Holland. Close to 80% of the globe was either directly or indirectly under European control. This process concurred with Enlightenment and the decline of religion as the center of European thought. While the religious component continued to be important to understand the colonies' past and legitimate colonial power, new concepts were replacing the justification that centered on God, which more frequently looked to reason. All around the globe, many of the peoples found by the Europeans in areas that were inhabited by societies with relatively low densities and that did not have an important political hierarchy were enslaved or wiped out, depending on the importance of the workforce and if there were special interests in the land itself. In other cases, the Europeans found large societies with a history that could be seen through important monuments, which forced the colonizers to interpret the past of the societies they had colonized.

These new forms of domination, to a large extent, gave rise to what would turn archaeology into a science. The discipline is not the result of colonial European expansion in its first phase, but clearly Enlightenment and need for ownership of the past helped to create scientific disciplines in charge of "explaining" the past. Archaeology and colonialism arose under the auspices of modernity (Thomas 2004). The common foundations of political justification or colonialism ever since come from enlightened thought based on reason. The enlightened thinkers in the second half of the eighteenth century questioned why some European countries had become civilized, manifested by the development of science, for example, and why others had not. This position led to the proposal of different explanations based on the natural sciences. Buffon, for example, suggested that the American peoples (the indigenous peoples) had recently arrived on the continent and, due to the prevalent humidity and heat, progress had been impeded. Other thinkers from the time, such as Pauw and Robertson, looked at the youth of the non-European peoples to explain their backwardness (Langebaek 2009). Civilization was an ascending scale, and it took time to reach the apex when there were natural obstacles that could make process either slow or impossible.

Sure enough, these ideas led to the immediate questioning of ruins in old civilizations in parts of Africa, Asia, and particularly the New World, and with this came a new interest in the nascent discipline of archaeology.

In the New World, the first archaeological expeditions were sponsored by the Spanish government, which was interested in demonstrating to the enlightened French and English that the Americas had given rise to real civilizations and that there was nothing in the nature of the continent that condemned its inhabitants (by now largely in some regions, the descendants of Spaniards) to perpetually remain in ignorance. They concentrated their efforts on excavating ancient monumental sites and analyzing accidental discoveries that demonstrated that the indigenous peoples had deep understandings of architecture, mathematics, and astronomy. Paradoxically, these same elements led to the descendants of Spaniards beginning to consider the Indians their "ancestors" and arousing their curiosity in pre-Hispanic monuments. They simultaneously highlighted the striking civilization before the arrival of the Europeans and how they had ruthlessly been destroyed (Cañizares-Esguerra 2002). Although the Latin American Creole elites were aware of the European discourses of the American peoples, they did not always copy the same dynamic. These elites created, popularized, and promoted structured discourses on the indigenous peoples that had once occupied the lands that were now theirs. They did this by deliberately ignoring certain uncomfortable aspects about the past and by glorifying others (Gnecco and Hernández 2008; Langebaek 2009; Tantaleán 2014).

In Europe, the rise of enlightened archaeology turned the cabinets containing ethnographic and archaeological curiosities that had been around for a long time into museums in which the European nations showed the complex relations empires had with ancient civilizations. A well-known example at the end of the eighteenth and beginning of the nineteenth century was the Napoleonic expedition to Egypt that brought antiquities to Europe, initiating interest in Near East societies at the same time colonizing them (Jeffreys 2003). Over time, the museums turned into national museums, and when there became significant interest in European races, new pan-Latin, pan-Slav, pan-Germanic outlooks of history developed. It very naturally occurred that there was more curiosity for the exotic: what came from the near East, far Asia, or Africa (Ballart 1997). This was the exact moment in which the African and Asian peoples began to be colonized by the European powers who were competing to gain access to raw materials and a workforce that was ever increasingly under the growing influence of the industrial revolution and the entrenchment of capitalism.

The New World, which was previously dominated by Spain but had been liberated by the Creole elites in the first decades of the nineteenth century, swiftly examined the "return to the past" that had functioned as an ideology to expel the Spaniards (Langebaek 2009). To begin with, the struggles against the discourses that had justified colonialism were also justified in terms of "recovering the past." Moreover, some leaders such as Simón Bolívar defined the Creole independence struggle as the assertion of native American societies despite the fact that in his private writings, there is unquestionable contempt toward the Indians (Favre 1986). Moreover, just after independence, Bolívar led a campaign to assimilate indigenous populations, which was even more successful than the Spanish regime's.

Several years after independence from Spain, the Latin American elites created a discourse that was completely detached from the pre-Hispanic tradition, which was more Europeanized. It was not until the end of the nineteenth century and the beginning of the twentieth that some members of these elites created "indigenist" narratives as a foundation to create nations that they defined as Indo-American or Mestizo, and this took place within a context of the racial debates. *Indigenism* per se arose in the first three decades of the twentieth century, and although it was based on an anti-colonial and profoundly national narrative, it did imply the reproduction of colonial values. Although it was particularly strong in Mexico, Bolivia, and Peru, its influence was felt throughout Latin America. It was manifested in art; it influenced a great deal of archaeological work and political movements of the time. *Indigenism*,

however, was deeply rooted in colonial traditions: it was a discourse about the Indians, but not produced by them (Ramos 1988; Favre 1998; De la Cadena 2000; Coronado 2009).

Developments in Latin America predated broader events around the globe due to colonial expansion in the late nineteenth century. In a context of nineteenth-century European powers, an important part of imperial supremacy was shown in the museums, which proudly displayed objects that had been brought from excavations in their colonies. The big empires, especially France, England, Germany, Russia, and Spain, sponsored scientific expeditions and obtained archaeological relics that were displayed in museums as evidence of not only their overseas power but also the prestige of archaeological science that was generously sponsored by kings and nobles. Objects brought from abroad, and sometimes even the "primitives" themselves, were exhibited, and they supported the thesis about different races that imperial nostalgia recognized as a vast field of exploration (Bendix 1997; Zimmerman 2001; Qureshi 2011). Some versions of evolutionism helped to justify European domination in large portions of the world in which the old civilizations were seen as failed attempts to make progress or showed evidence that colonized societies had not achieved a degree of civilization.

Archaeology and Colonialism Today

After World War II, the past transformed into something greatly controversial in which nationalism, sectarianism, and exclusion had frequently been the protagonists. The imperial rhetoric that had justified European expansion during the nineteenth century and the North American expansion during the twentieth century had not disappeared (Thomas 2000; Willems 2009) although they had in some cases transformed into elite local discourses rather than direct foreign intervention (Gnecco and Hernández 2008). A great deal was replaced by a renewed and complex narrative that reclaimed native societies and uncovered the harm caused by new colonial practices. The legacy of Western colonialism is complex and diverse: it implies new nationalisms and also new colonial projects which belong to neither Europe nor North America. Subtle forms of cultural dominance, such as those who maintain that the Indians from the New World are actually of Chinese origin or that they were "discovered" by Chinese expeditions, are examples. Local powers that have filled the European imperial vacuum with their own desires for dominance are all phenomena that need to be studied to give critical archaeology a relevant position in the world today.

In Africa, the existence of ancient kingdoms has been a source of inspiration for recently liberated nations in response to a mythical unity and resistance to the change with which the Europeans characterized precolonial societies (Shepherd 2002; Schmidt and Waltz 2007). Within both developed and non-developed countries, globalization has encouraged minority ethnic groups to defend their identities using the remote past, which has generated new relationships not only with State agencies but also with archaeologists. As a case in point, in Colombia, the Political Constitution of 1991 has promoted the development of new "native" identities and the *re-indigenization* of societies that were considered until recently as *campesino* (Gnecco and Hernández 2008). Even in urban contexts, communities have emerged that claim to be native: decedents of the sixteenth-century inhabitants. These indigenous groups frequently endeavor to reconstruct territorial, "ancestral," domains of the past, and they also engage in campaigns to recover their native language, ritual, and information about distant origins. These stories are repeated throughout the Americas, Africa, and Asia as States recognize ethnic diversity and leave ownership of the past to more regional groups (Glover 2010). In the Middle East, archaeology serves the purposes of Zionism to justify the Israeli occupation of Palestinian territories, but it also serves the purposes of those that held political power in Egypt, Syria (particularly the Alawites), Iraq, and Iran (Abu-El-Haj 1998; Guillot 2010). After independence, all these countries nationalized archaeology, and, especially when secular societies were in place, archaeology played an important role in creating narratives of power.

Future Directions

Interest in confronting archaeology's past and present in terms of the political agenda that it has served has implications for any practicing archaeologist. In its most extreme form, postcolonialism has led to a divide between archaeological fieldwork, which is focused on answering questions about the past, and the historical and sociological reflection on the political content of the practice. The reflection on the political dimensions of colonialism and its relationship with archaeology was born, in part, due to the same debate between relativism and scientific optimism: the latter being related by some with colonialism and the former with its criticism (Shanks and Tilley 1987). Some archaeologists have been able to actively engage in political issues while continuing to gain a better understanding of the past, for example, V. Gordon Childe and Bruce Trigger. There have been various in-between spaces that have opened after the debate on the relationship between archaeology and colonialism, which have been very productive, for example, the effort to work with natives in certain regions and programs that are orientated toward training local archaeologists who can work on equal terms with archaeologists from Western countries and explicit exercises to make archaeology politically engaged. Indeed, many more solid and interesting "histories of archaeology" have been written (Schnapp 1996; Beck 1998). It is true that one area of academia has disclaimed the scientific pretentiousness of the discipline and has concentrated its efforts solely on establishing the way in which archaeology has converted into a hegemonic power that should be exposed. Some frequently totally renounce the legitimacy of having an understanding of the past from a point of view different to what the "natives" have constructed. And, there are also those who maintain that the past can be examined by archaeologists who are upholding political neutrality. However, political use of any archaeologist's work is completely out of their hands; it enters the public domain and, therefore, acquires a significance that is not neutral and that cannot be controlled.

Many have not lost the hope that being able to understand the past is a legitimate aspiration; they want that "knowing what really happened" in the past has the potential to be enormously politically liberating (Trigger 1994). Ultimately, "what really happened" or, at least, what was most likely to have happened should not be a cause for worry for those who want to critique what they consider to have happened to the detriment of the whole of humanity and especially to humanities' weakest members.

[3]Digital History Center, The Colonial Williamsburg Foundation, Williamsburg, VA, USA

Basic Information

The Colonial Williamsburg Foundation (CWF) is a not-for-profit educational organization dedicated to the preservation, interpretation, and presentation of Williamsburg, the restored eighteenth-century capital of Virginia. This town-sized (301-acre) living history museum tells the story of becoming American by way of historic house tours, trades demonstrations, and through Revolutionary City, an interactive street theater program that depicts life during the revolution as told by the residents of eighteenth-century Williamsburg. The Art Museums of Colonial Williamsburg and the DeWitt Wallace Decorative Arts Museum feature British and American furniture and art from 1670 to 1830, while the Abby Aldrich Rockefeller Folk Art Museum is home to the nation's premier collection of nineteenth- through twenty-first-century American folk art. Colonial Williamsburg is committed to expanding its thought-provoking programming through education outreach on-site and online.

Williamsburg is located in Virginia's Tidewater region within an hour's drive of Richmond and Norfolk and 150 miles south of Washington, DC (website: www.history.org).

Major Impact

Colonial Williamsburg has been central to the development of North American historical archaeology since the late 1920s. Starting with an inventory of 88 standing eighteenth-century structures, workmen and architects began the process of reconstruction by carefully uncovering belowground footings and foundations and recovering associated architectural elements with the purpose of re-creating, as closely as possible, Virginia's second colonial capital. An extensive campaign of architecturally focused excavations was continued through the 1950s by Colonial Williamsburg's Architecture Department. Whole blocks were "cross-trenched," a process involving regularly spaced, foot-wide trenches dug diagonally to the north–south Baroque grid pattern of the city. When a building footing or foundation was encountered, it was exposed, mapped, and photographed. By the late 1950s, an estimated 75% of Williamsburg's historic area had been cross-trenched, and more than 300 buildings were ultimately reconstructed based on physical evidence found through that cross-trenching. While quite successful in locating structures for

potential reconstruction, this type of architecturally based excavation shed little light on the lives of Williamsburg's residents.

In 1957 British archaeologist Ivor Noël Hume was hired as the foundation's first full-time historical archaeologist. Under his leadership, excavation was separated from the Resident Architect's Office and evolved into one of North America's first and most renowned programs in the emerging discipline of historical archaeology. Noël Hume was also very influential in the establishment of the Society for Historical Archaeology and hosted its first meeting in Williamsburg in 1968. In addition to expanding the scope of archaeological research beyond the hunt for architectural remains, Noël Hume instituted two crucial changes to the excavation program: open-area excavation and the systematic retrieval of portable archaeological evidence including artifacts, faunal remains, and botanical material. Ivor Noël Hume and his wife Audrey skillfully combined the evidence recovered from the ground with the plethora of historical documentation surrounding Williamsburg, to create meaningful portrayals of life in the eighteenth-century capital.

In 1982 Dr. Marley R. Brown III followed Noël Hume as Colonial Williamsburg's Director of Archaeological Research. Under his leadership, CWF archaeology adopted a more anthropological approach and expanded its research to include a diachronic perspective to changes in the landscape. Research involving the creation of Williamsburg's urban environment, seventeenth-century settlement patterning, colonial foodways, the role of African Americans, intra-site spatial patterning, an international outlook toward comparative colonialism, and multidisciplinary approach to geophysical, faunal, and environmental analysis expanded the role of archaeological research considerably.

By the 1980s, the National Historic Preservation Act stimulated a wave of compliance-oriented investigations that both influenced and complemented the existing CWF program of research-based investigations. Important sites investigated included the Peyton Randolph Outbuilding Project, Shields Tavern, the Everard House, the St. George Tucker Garden, the Douglass Theater, the James Wray carpentry yard, the John Page manor house, and the seventeenth- and eighteenth-century components of Rich Neck Plantation to name a few. Excavations at seventeenth-century sites at Martin's Hundred were also continued shedding new light on the scale and scope of colonial settlements beyond Jamestown Island including indentured servitude and the early adoption of enslaved African labor on small colonial farms such as Atkinson site.

Another significant hallmark of this period was the partnership between Colonial Williamsburg and other heritage and academic institutions, both domestic and foreign, to explore the interrelationships between disparate British colonies. In particular, a cooperative agreement in the early 1990s with the National Park Service led to the Jamestown Archaeological Assessment culminating in a seven-volume report encompassing the archaeology, environment, history, geology, and the potential of the National Park Service's 60-year archaeological program on Jamestown Island as well as two important doctoral dissertations (Horning 1994; Wehner 2006). The CWF/NPS cooperative agreement also led to archaeological surveys and evaluations at George Washington Birthplace National Monument, Yorktown (Colonial National Historical Park), Appomattox Court House National Historical Park, City Point (Petersburg National Battlefield), and Shenandoah National Park.

Meanwhile, CWF archaeologists, working in partnership with the Bermuda National Trust and the Bermuda Maritime Museum, conducted excavations and documentary research at various sites in Bermuda. Also in the 1990s, archaeologists from CWF carried out work in Bridgetown, Barbados, in conjunction with the National Trust of Barbados. Architectural research in Bermuda and Jamaica has continued under the direction of architectural historian Edward A. Chappell (Chappell 2009).

A particularly enduring legacy of the archaeological program in the late twentieth century was the establishment of the annual field school in historical archaeology held in conjunction with the Department of Anthropology at the nearby College of William and Mary. Since 1984

thousands of undergraduate and graduate students, including some of today's best-known scholars, received their formative training in archaeological fieldwork while working alongside Colonial Williamsburg's professional staff.

In 2008, Colonial Williamsburg's archaeological research staff and the foundation's Architectural Research Department became a single department under the leadership of architectural historian Edward A. Chappell. The consolidation reflected the increasingly interdisciplinary nature of archaeological work in the twenty-first century and the changing nature of CWF's public programming. The staff also works closely with archivists, curators, conservators, as well as media education specialists, digital historians, and cultural anthropologists (Fig. 1).

Colonial Williamsburg Foundation (CWF): Historical Archaeology, Fig. 1 Archaeology of a late eighteenth-century dairy at Charlton's Coffeehouse

A detailed and updated description of recent archaeological projects can be found on the Colonial Williamsburg website: http://research.history.org/Archaeological_Research.cfm.

Current research areas:

- Colonial Williamsburg is committed to a program of public outreach that promotes a preservation ethic and conveys what archaeology is and what we have learned from its practice. Programs that communicate the stewardship of archaeological sites as "cultural heritage resources" and ones that focus on the central work of archaeologists as a multifaceted process of learning about the past are key models used in CWF public archaeology curricula. The foundation has developed hands-on "Discovering the Past" programs, aimed at school-aged groups that uses volunteers and regular staff to help children and young adults begin to think as archaeologists do about the past and their own surroundings. All programs have a central theme that attempts to accurately describe the work of archaeologists while maintaining the value of archaeological sites by avoiding the suggestion that anyone can dig without extensive training. Training of that nature is provided through the accredited field school in historical archaeology.
- Colonial Williamsburg's archaeological projects and resources on African Americans, generated from the excavations of mixed-racial and entirely African-American sites, are central to historical interpretation and reconstruction. From the late 1970s, research on eighteenth-century plantations like nearby Carter's Grove, Rich Neck, and Palace Lands (Fig. 2) and sites of later dates such as the Quarterpath Road and the Polly Valentine House have generated a wealth of information contributing to a firm database of resources to help the comprehensive study of the social, political, and economic diversity of Virginia during the colonial and even early modern periods. Work at multiracial sites in the historic area including the Ravenscroft lot and the Public Armory has sought to understand "cultural differences" relating to African Americans that

Colonial Williamsburg Foundation (CWF): Historical Archaeology, Fig. 2 Archaeological field school at an African-American slave quarter on the Palace Lands in Williamsburg

can be addressed archaeologically. With a number of substantial, accredited studies, the archaeological program prioritizes research on key topics including slave living and working areas, faunal and botanical studies of foodways and medicine, master–slave relations, as well as factors that affected the acquisition, use, and disposal of certain material items (Edwards-Ingram 2005).

- Colonial Williamsburg and the College of William and Mary have collaborated on the Historical Archaeology of Native Americans. The College of William and Mary's intent to renovate the eighteenth-century Brafferton building, a structure used to house the college's eighteenth-century Indian school, led to an archaeological investigation of the site through the joint CWF/W&M archaeological field school in the summer of 2011. Significantly, the Brafferton represents the only documented location within the limits of eighteenth-century Williamsburg where Native Americans were the primary inhabitants, and the site's 2011 investigation indeed recovered intriguing material evidence on Native Americans living at the college. Also notable was the fact that the Brafferton represented a new level of community engagement for CWF's archaeological research staff, again reflecting recent trends within the broader discipline to engage stakeholders beyond the professional archaeological community. Building upon both community-based and indigenous archaeology models developed over the last decade, the Brafferton Legacy Group, an advisory body made up of William and Mary Native American alumni, offered guidance on how the excavations might provide an opportunity to reforge connections between the college and contemporary Native American tribes.
- Using multiple analytical scales, environmental archaeology draws on faunal remains, phytoliths, pollen, macrobotanicals, and parasites to reconstruct the colonial town's biotic and cultural landscape. CWF zooarchaeological researchers have amassed a large database of urban and rural sites from which they have reconstructed the provisioning system that fed urban populations. Through the lens of landscape ecology and animal behavior, they have reconstructed how colonists adopted native horticultural practices to produce the commercial crop tobacco and develop an open woodland husbandry system. Palynological and phytolith studies have produced evidence of forestation in the eighteenth

century, followed by a decline in pine pollen and an increase in weedy plants associated with disturbed soils. On the household level, numerous faunal, pollen, macrobotanical, and parasite studies have identified household subsistence practices of all walks of life, the elite, enslaved, tradesperson, and more (Walsh et al. 1997; Mrozowski et al. 2008). Current work is continuing to expand our understanding of Williamsburg by reconstructing garden and other cultural landscape features in urban houselots and by identifying broad regional and neighborhood changes in the biotic landscape (Fig. 3).

- *Virtual Williamsburg*, an interactive 3D computer model of Williamsburg currently in development (Fig. 4), reflects the latest archaeological and architectural research. Virtual heritage is an increasingly important expression of a cultural heritage site's state of research and one that is also creating new paradigms for understanding the past (Kalay et al. 2008: 9). *Virtual Williamsburg*, which is being built neighborhood by neighborhood, will recreate the colonial cityscape of Williamsburg in 1776 on the eve of the American Revolution. The assimilation of multiple archaeological datasets to create the virtual reconstruction is providing new insights into the town's history and development. The model draws upon a range of material culture and archaeologically derived topographical and environmental data are being combined to reconstruct the eighteenth-century landscape virtually. The digital reconstruction will be used to create a range of educational media for exploring the town during this important period in its history and to enhance the on-site guest experience. The first neighborhood being virtually reconstructed – the east end of town – includes significant buildings that have not been physically reconstructed, such as the second Capitol and the Douglass Theatre, and is being modeled in conjunction with the University of Virginia's Institute for Advanced Technology in the Humanities. Funding for *Virtual Williamsburg* and 3D modeling at Colonial Williamsburg has been provided by the Institute of Museum and Library Services, the National Endowment for the Humanities, and the Andrew W. Mellon Foundation.

Archaeology at Colonial Williamsburg in the twenty-first century continues as it has in the past, by taking an up-to-date interdisciplinary approach to the historical archaeology of the British Atlantic World and the Chesapeake Region.

Colony of Avalon Archaeological Site

Teal Hranka
School of Archaeology, College of Arts and Celtic Studies, University College Dublin, Belfield, Dublin, Ireland

Basic Information

Colony of Avalon, Ferryland, Newfoundland, Canada.
www.colonyofavalon.ca

Major Impact

The Colony of Avalon archaeological site, nestled in the community of Ferryland, Newfoundland, Canada, and located on a major promontory along the eastern coast of the Avalon Peninsula roughly 80 km south of St. John's, represents one of the earliest attempts at English settlement in the New World.

The modern town of Ferryland has a history of occupation that extends backward in time more than 500 years. The first reference to the place is found on Giovanni Verrazano's 1529 map of the world, on which the familiar Newfoundland headland is labeled as "Farilham." The first notation by the English, in the 1590s, refers to the harbor as "Farillon." Either name can likely be traced as a corruption either of *farelhao*, the Portuguese nomenclature for steep rock or point, or of the French word *forillon*, meaning "cape", or "point."

The Colony of Avalon archaeological site provides us with a record of a long and rich cultural history. Early exploitation of the rich Newfoundland fishing grounds began in the early 1500s. The early fishery was a shore-based operation, whereby fishermen deployed to the sea in day-to-day expeditions from camps along the shore. The conspicuous Ferryland headland, jutting prominently into the North Atlantic, boasted a harbor with easy access to the fishing grounds, and extensive cobblestone beaches for drying catch.

Throughout the sixteenth and seventeenth century, Portuguese, Spanish, Basque, French, and West Country English fisherman are known to have been exploiting the resources of Newfoundland's waters. After 1565, English involvement in the Newfoundland fishery dramatically increased as European economic conflicts severely affected both the Spanish and Portuguese fisheries, and an economic shift in France's transatlantic fishery shifted much of its massive contingency to a "wet" offshore fishery. These two processes opened the way for England to officially dominate much of the inshore niche from the end of the sixteenth century onward (Matthews 1973; Pope 2004). By the 1600s, the English fishery was firmly established on the peninsula, and the first attempts at permanent settlement quite inevitable.

Intermingled with the residual fragments of migratory European fishermen, archaeologists have uncovered evidence of Newfoundland's now-extinct native Beothuk people at Ferryland, including bifaces, projectile points, stone tools, and Beothuk hearths. The Beothuk campsites have been found in association with sherds of early European ceramic wares, suggesting a concurrent exploitation of the resources at Ferryland during the sixteenth century, and attesting to the importance of the site at this time, although notably, archaeological evidence indicates a *terminus ante quem* for Beothuk presence at the site of no later than 1580 (Gaulton 2001).

The colony itself was variously referred to across time as Avalon, the Pool Plantation, and Ferryland. In 1620, George Calvert (later the first Lord Baltimore, whose heirs would come to settle St. Mary's City in modern Maryland, U.S.A.) purchased a tract of land between modern-day Calvert and the headland between Aquaforte and Fermeuse from Sir William Vaughan, whose earlier attempts to start a settlement in the area had been unsuccessful. Construction of the settlement of Avalon, as Calvert would come to call his colony, began on August 4, 1621, when Captain Edward Wynne, acting on behalf of Lord Baltimore, arrived in Newfoundland along with 11 other settlers and erected a series of buildings, including a 13.3 by 4.5 m dwelling with a semi-attached kitchen and parlor, as well as tenements, a forge, saltworks, a brewhouse, a hen house, a

well, a wharf, and a defensive palisade, concentrated around a sheltered inner harbor referred to as "The Pool" (Gaulton and Tuck 2003; see also Gaulton and Miller 2009). These buildings established the site as a permanent settlement, one that would eventually become the predominant colony in Newfoundland throughout much of the seventeenth century.

The colony has an intriguing and interesting history. In the winter of 1622/23, thirty-two additional settlers arrived and by the middle of the decade, roughly 100 settlers inhabited the colony of Avalon, although Baltimore himself left Ferryland and its "intolerable cold" within a year of his own arrival in 1627, leaving the colony in the hands of a trusted representative (Cell 1982; see also Miller et al. 2011). In 1637, a syndicate headed by Sir David Kirke was granted administrative proprietorship of Newfoundland through the close connections of its members with the court of Charles I. In 1638, Kirke, along with his wife Lady Sara, their three sons, and a group of about 100 new settlers, arrived in Ferryland to take advantage of this grant. Exploiting Lord Baltimore's absence from the settlement, Kirke evicted the Calvert's representative, Captain William Hill, and expropriated Ferryland. Kirke and his family took up residence in the mansion house, and Calvert's settlement came to be known as the Pool Plantation (Gaulton and Tuck 2003). A series of lawsuits ensued between the Calverts and the Kirkes as both parties pressed for ownership, and in 1651, Kirke was called to England for an official inquiry into the administration of Newfoundland and his activities there (for further context, see Pope 1998). Kirke lost proprietorship of Newfoundland and was forced to forfeit his lands and possessions to Cromwell's Commonwealth. In spite of this, and regardless of the government's appointment of a new commissioner of the colony in 1653, Lady Sara Kirke and her sons remained at the settlement and Lady Kirke eventually became one of the most successful fish merchants in the area until her death in the 1680s. Kirke himself died in prison in 1654.

The community is known to have thrived until the third quarter of the seventeenth century, when wars between the European countries spilled over into Newfoundland. Ferryland was subjected to an unopposed attack by four Dutch ships in 1673, and later to a more well-executed attack carried out by the French on September 21, 1696, as France competed with England to assert its own claims on Newfoundland and its fishery. When the inhabitants of Ferryland refused to swear allegiance to the French king, the colony was destroyed. Following several years of peace, France and England renewed their war in 1701, and the colony was attacked twice more by the French, in 1705 and 1708. In 1713, Queen Anne's War finally ended, culminating with the Treaty of Utrecht. The provisions of the treaty stipulated that France relinquish the Island of Newfoundland to the British. A long period of peace followed the signing of the treaty, and Ferryland's colonials remained safe from further collateral damage by the wars. Intriguing archaeological data from this period reflects the extent of the damage wrought during this era and provides us with an opportunity to explore how these events impacted and changed the social and economic context of life at the colony. While much of the archaeology at the site to date has focused on the Calvert and Kirke eras at the colony, research continues to expand our understanding of the development of the colony into the eighteenth century as well.

While the existence of the Colony was never lost from either history or from local memory, the actual location of the site was undetermined until the last two decades. Archaeology at Ferryland began in the late nineteenth century, when, based upon information gleaned from historical records, the antiquarian M.F. Howley unearthed several artifacts while attempting to pinpoint the coordinates of the original settlement. Limited excavations followed in 1937 by Carnegie Institute entomologist Stanley Brooks, in 1959 by Russell Harper on behalf of the Historic Sites and Monuments Board of Canada, in 1968 by the Memorial University Archaeology Unit, and in the 1970s by Robert Barakat. Intensive excavations at the site began in the mid-1980s by Memorial University and have continued on an ongoing basis since 1992 for up to 20 weeks each summer.

Archaeological assemblages have contained a remarkable collection of seventeenth and eighteenth century artifacts, and excavations have revealed the scale, as well as attested to the significance, of the site. Defensive works in the form of a

20-ft-wide ditch and 20-ft-wide rampart border the eastern side of the colony, with a large bastion at the south end of the fortification ideally placed to monitor ocean traffic and to support ordnance in defense of the colony (Gaulton and Miller 2009). The colony features a large quay, a massive stone seawall, and an impressive stone storehouse with interior dimensions of 16 by 56 ft. on a waterfront terrace immediately to the south of Ferryland's inner harbor. A well-built stone wall separates the waterfront terrace from a higher terrace to the south upon which a series of dwellings, including a group of interconnected structures which form the impressive "Mansion House," as well as tenements, outbuildings, a forge, and a brewhouse and bakery have been excavated. A cobblestone street, 13-ft wide and 400-ft long, spans the distance of the original colony's boundaries, and connects the structures of the upper terrace to those of the waterfront on the terrace below. Archaeologists have surmised that the colony in its entirety must have resembled one of the small port towns of the West Country with its layers of buildings and cobbled walkways, courtyards, and work areas (Gaulton et al. 2011).

The English colony of Avalon at Ferryland, Newfoundland, is a site extraordinarily rich both in history and in archaeological remains. The site continues to provide a rich archaeological heritage of the seventeenth and eighteenth century in Ferryland, and a window into one of the earliest settlements in the New World. Significant discoveries continue to occur today. Supported by the Colony of Avalon Foundation, the facility includes an interpretation center with guided onsite tours, a conservation laboratory, a collection storage area, a gift shop, a reproduction of a seventeenth century kitchen, and three heritage gardens.

Commingled Remains

Field Recovery and Laboratory Analysis

Bradley Adams
Forensic Anthropology, Office of Chief Medical Examiner, New York, NY, USA

Introduction and Definition

The term "commingling" refers to the intermixing of remains from more than one individual (Fig. 1) and, when present, is a challenging component of many anthropological analyses. The study of commingled remains may pertain to an

Commingled Remains, Fig. 1 Archaeological excavation showing commingled human remains *in situ* (photograph courtesy of John Byrd)

archaeological context or a forensic context. Within the archaeological context, the focus of study could be faunal (i.e., nonhuman) remains or human remains. Within the forensic realm, discussions of commingling usually refer to the intermixing of human remains, such as may occur from a mass disaster or in cases of mass graves resulting from periods of political, ethnic, or religious violence. Regardless of whether the context is archaeological or forensic, commingling of remains will complicate every facet of the process from recovery to final disposition. The focus of this section will be an overview of field recovery and laboratory analysis of commingled *human* remains, although there is clearly overlap with the recovery and analysis of faunal remains.

Historical Background

It is often the role of an anthropologist to document and attempt to resolve commingling. An early example of research into the forensic analysis of commingled remains is an article by Charles Snow (1948) who was the first physical anthropologist at the US Army's Central Identification Laboratory in Hawaii. In this article, Snow outlined protocols used in the anthropological analysis of US war dead from World War II. Although there have been technological advances since that time, most of the methods used for dealing with commingled remains are still relevant today. More recent publications on commingled human remains include Ubelaker (2002), Byrd and Adams (2009), Adams and Byrd (2008, 2014), Osterholtz et al. (2014), and a special edition of the journal Forensic Anthropology (2019), all of which provide comprehensive lists of additional references on the topic.

Key Issues

The primary considerations associated with commingled remains include field recovery and laboratory analysis. Field recovery deals with the documentation and collection of remains, while laboratory analysis primarily deals with sorting and quantification. As the number of commingled individuals increases, so does the complexity of the investigation and the skills and resources needed for case resolution. The analytical complexity is also tied to the condition of the remains. As the state of preservation declines, the complexity of the recovery and/or analysis increases. The condition of the remains will vary depending on the circumstances associated with death, depositional context, and the amount of time elapsed between death and recovery. States of preservation may range from fleshed to skeletonized, and from intact to fragmentary. Taphonomic changes, such as thermal alteration (Warren and Schultz 2002) and weathering, may further complicate the analysis of commingled remains. The degree of commingling can vary widely from situations that are relatively straightforward, such as intact remains and a small number of individuals, to those that are extremely challenging, such as a large number of individuals and/or extensive fragmentation.

It is possible to broadly categorize commingling scenarios into two types: small-scale and large-scale. Small-scale commingling exists when there are not many disassociated body portions and/or the overall number of individuals is small. Even if the overall number of individuals is large (such as a mass grave), the degree of commingling may still be considered to be small-scale if the skeletal elements are mostly articulated upon their recovery. Large-scale

commingling involves large numbers of individuals whose body parts are intermixed, or it may represent scenarios with extreme fragmentation. For example, a plane crash with a relatively small number of individuals may become a large-scale incident if the body fragmentation is extensive since each separate fragment initially needs to be treated as potentially coming from a different individual. Large-scale commingling often necessitates a greater reliance on DNA analysis and presents numerous logistical challenges, such as data management and analytical space.

The September 11, 2001 terrorist attack on the World Trade Center (WTC) in New York City represents an example of an event that resulted in large-scale commingling. There are 2753 known victims and over 21,000 human remains have been recovered to date. Anthropological methods have played an important role in the various aspects of recovery and analysis, but the high level of fragmentation necessitated a strong reliance on DNA for victim identification. At the Office of Chief Medical Examiner in New York City, the successful resolution of commingled WTC remains has been due to a collaborative effort between the Forensic Anthropology and Forensic Biology Departments (Mundorff et al. 2014).

Field Recovery

Familiarity with archaeological excavation and site mapping techniques are important factors for the successful recovery of commingled human remains (Dirkmaat and Adovasio 1997; Haglund 2002; Schmitt 2002; Skinner et al. 2002). Documentation (three-dimensional location) of the provenience of the remains and associated artifacts can prove critical for the subsequent laboratory analyses. It is important to remember that once remains are collected from the field, this important spatial information will be lost unless maps, notes, and photographs are completed while the remains are in situ (i.e., in their original position).

Laboratory Analysis

In the laboratory, the two primary objectives will be to sort the commingled remains into specific individuals and to quantify the overall number of dead. Within the forensic context, attempts will be made to identify the remains to a missing individual and return them to the next of kin. For situations with known or suspected commingling, all remains should initially be considered as coming from a separate individual unless they can be shown to be attached by soft tissue or to conjoin to another piece at a fracture site. As stated above, the context in which remains are found will often provide critical information in the sorting process, such as when body parts are found in correct anatomical position despite being disarticulated from the body.

The first step of the sorting process involves an inventory and determination of body part representation. As part of this step, fragmentary remains should be conjoined to the greatest extent possible as this will assist in overall sorting process. When working with fragmentary, fleshed human remains, it may be difficult to grossly recognize the full extent of commingling. Radiography can be a useful tool in the recognition of commingling depending on the type of incident and preservation of the bodies (Viner 2014; Goodman and Edelson 2002).

After an inventory of the skeletal elements is made and reconstruction completed, there are numerous anthropological sorting techniques that may be used in the resolution of commingling. In essence, these techniques are used to rebuild individuals. They include visual pair-matching (the association of homologous elements based on similarities in morphology) (e.g., Legarde 2019), articulation (formation of a congruent joint or juncture with another element), process of elimination (determination that certain remains could originate from one, and only one, individual), osteometric comparison (use of statistical models to objectively compare size and shape relationships between elements based on measurements) (e.g., Byrd and Legarde 2018; Thomas et al. 2013), and taphonomy (similarities and differences in postmortem preservation). Components of the biological profile (e.g., age, sex, and stature) may also be useful in the sorting process. The majority of these sorting

procedures are not stand-alone techniques and they are most relevant for small-scale incidents. For best results, they should be used in conjunction with each other, as well as with the contextual scene information. Finally, anthropologists utilizing these techniques should have a strong background in skeletal anatomy along with an understanding of bone morphology and human variation. Although not an anthropological technique, the comparison of postmortem DNA profiles also provides a powerful means of segregating remains, as mentioned above with the WTC example, and may be a primary means of sorting/re-association with large-scale and very fragmentary scenarios.

When working with commingled human remains, the goal of quantification is to estimate the total number of dead. Determination of the number of individuals usually occurs after the re-association process is complete (i.e., conjoining fragments and sorting into specific individuals). Components to consider when determining the appropriate quantification technique include bone preservation and scale of the incident. Probably the more important of the two is preservation since extremely fragmentary or poorly preserved remains may not be amenable to any accurate quantification technique.

For interpreting population size from a skeletal assemblage, the Minimum Number of Individuals (MNI) presents the minimum estimate of the number of individuals that contributed to the sample. Within anthropology, this technique is frequently used for estimating the number of individuals due to its ease of calculation. The most common variant of the MNI is simply calculated by sorting the bones by side and element and then taking the greatest number as the estimate. In order to deal with fragmentary remains, specific segments of an element (e.g., proximal humerus) can be used for the calculation of the MNI. Every fragment must share a specific landmark to ensure that fragments do not originate from the same skeletal element. The basic principle of an MNI estimate is to avoid counting the same individual twice.

Other quantification techniques are available for the analyst. One alternative method is the Most Likely Number of Individuals, or MLNI (Adams and Konigsberg 2004; Konigsberg and Adams 2014). This technique is used to estimate the actual number of individuals, as opposed to the minimum number, and research has shown that this can be an effective method (Palmiotto et al. 2019). The MLNI is calculated based on the number of paired and unpaired bones (as opposed to the MNI which is usually not dependent on pair-matching). In addition, confidence intervals can be calculated for the MLNI estimates. For proper use of the MLNI, preservation must be good since it is critical that elements can be accurately pair-matched. For situations where there has been random loss of body portions, the MLNI estimates should provide the most accurate estimates of the true population.

Final Considerations

For the anthropological analysis of commingled remains, it is imperative that appropriate methods are utilized during field recovery and laboratory analysis. Otherwise, important information may be lost. For forensic investigations, the successful resolution of commingling will be tied to personal identification of the decedents and reassociation of the greatest amount of remains possible. Ethically challenging decisions pertaining to the treatment of commingled remains will have to be determined within the forensic context (Kontanis and Sledzik 2014; Wagner 2014). Many of these decisions will likely fall outside the purview of the anthropologist, such as the scope of the effort (e.g., will every fragment be analyzed for reassociation or will there be a size parameter established for analysis) and the disposition of unidentified remains (e.g., the fate of common tissue which is not linked back to a specific decedent).

Communicating Archaeology: Education, Ethics, and Community Outreach in North America

Sherene Baugher
Cornell Institute of Archaeology and Material Studies and the Department of Landscape Architecture, Cornell University, Ithaca, NY, USA

Introduction

Archaeology has always been a dynamic field with amazing discovers about the past being reported to the public. Over time there has been a transformation in communicating archaeology to the public from eighteenth-century museums as "cabinets of curiosities" to twenty-first-century anthropology/archaeology and history museums. Archaeologists in Canadian and United States universities, museums, government, and nonprofit organizations have been faced with the challenges of presenting archaeology to the public. Beyond museum exhibits, archaeologists give public lectures, have tours of their sites, write articles and pamphlets for the public, present programs for school-age children, and undertake excavations with students and adult volunteers. In the diverse ways in which North American archaeologists engage the public, how do ethics and community collaboration fit into the picture of public archaeology, especially in the realm of education? The focus of this entry is on community collaboration in educational outreach.

Historical Background

Nothing exists in a vacuum. Archaeologists' acceptance of community outreach and willingness to engage the public reflected trends found throughout Canada and the United States in the later part of the twentieth century. Educational efforts to reach out to the public were also taking place in affiliated fields such as museum studies and history, and these have affected our work. The 1960s and 1970s were the early years of the new social history. American historians were focusing on women, African Americans, American Indians, various ethnic minorities, and the working class – the people often overlooked in traditional historical research. The goals were to enlarge our view of history and bring to life the forgotten history of people without power – to tell the history of all Americans. With this interest in new areas of social history and outreach work, archaeologists such as James Deetz became involved in bringing archaeology to the public through outdoor museums (Deetz and Deetz 2000). In 1978, Deetz pioneered the idea of first person interpretation at Plimouth Plantation, in Massachusetts, which was later used at other living history museums.

Indoor museums were also trying to engage the public and promote museum education programs to a broader public. In the early 1970s, Thomas Hoving, then Director of the Metropolitan Museum of Art in New York City, championed opening the doors of fine art museums to the public regardless of socio-economic background, race, ethnicity, or religion. The goal was to dismiss the idea of the museum as a place for just the highly educated elite. Hoving argued for new types of exhibits that would be educational and would discuss the artifacts in their cultural contexts. The first of his new "block-buster" shows was the King Tut traveling exhibit in 1976. This exhibit excited the public about archaeology, and museum attendance rose dramatically. History and Anthropology museums were also challenged to design exhibits with public outreach components and to provide better programs in museum education.

In the 1980s, agencies such as the National Park Service were hiring professional writers to take data from the technical records and write archaeology articles and books for the public, especially for teachers (Jameson 2004). State agencies such as the Delaware Department of Transportation were requiring Cultural Resource Management firms (CRM) to produce both technical reports and "popular" reports for the public. To encourage public education,

professional organizations such as the Canadian Archaeological Association, the Society for American Archaeology, and the Society for Historical Archaeology created public archaeology committees and public archaeology columns in their professional newsletters and/or on their web sites. In 2000, the Society for American Archaeology's *Ethics in American Archaeology, 2nd edition* stressed the need for public education. In 2005, the Society for Historical Archaeology produced a book, *Unlocking the Past,* to present an overview of North American archaeology for the public. In addition, there are a growing number of books on state and city archaeology written for the educated public as the target audience.

By the 1980s, National, State, and Provencal Parks in North America were providing the public with educational tours of archaeological sites. There were heated debates over site tours: would it be educational, would it protect the sites by creating public interest, or would it make the sites more susceptible to looting? The looting did not happen and the tours did create excitement and interest in the archaeology and the sites (see articles in Jameson 1997). By the 1990s sites tours were becoming an accepted way of presenting archaeology to the public. For example, the public has been visiting the yearly excavations at Jamestown in Virginia since 1994.

Key Issues and Current Debates

Ethical Discussions

By the 1990s and into the twentieth-first century, archaeologists have debated the merits of public outreach and public archaeology. How should we engage the public? What should be the composition of these educational programs? Initially these programs were based on what the archaeologist wanted to present to the public or thought that the public needed (Jameson 1997). Archaeologists started to discuss the values of working collaboratively with scholars in other professions, such as museum curators and museums educators. For archaeologists working on historic sites, especially heritage sites, the work involved collaborations with historians, historic preservationists, architectural historians, and landscape architects. This cooperative work enhanced both the quality of the public programs and the underlining interdisciplinary research (Derry and Malloy 2003; Jameson and Baugher 2007).

The early outreach efforts often involved archaeologists working in isolation from community groups. It was the archaeologists and the interdisciplinary team of scholars who decided, without input from community members, what messages the public needed and wanted. Questions, such as who is the target audience, and what questions do they want answered, were often not on the archaeological radar screen. But archaeologists started to move out of the isolation model and partner with community members in order to develop more meaningful public programming. The major shift in archaeological outreach was moving from presenting material *for* the public to working *with* the public. But in working with the public there had to be a major shift from a hierarchical to a collaborative model.

One of the key ethical issues of the late twentieth century and the early twenty-first century has been the question of "who controls the past." In 1990 in the United States, the passage of the Native American Graves, Protection, and Repatriation Act (NAGPRA) altered the way archaeologists work. Native Americans have and continue to demand the right to protect their sacred sites and burial grounds and to repatriate both their ancestors' remains and their objects of cultural patrimony. Native Americans and First Nations no longer want to be research subjects and they do not want archaeologists to control the interpretations of the past. NAGPRA helped to stimulate collaborative work between archaeologists and Native Americans. By the late 1990s, two federally funded journals, *CRM* and *Common Ground* (formerly the *Federal Archaeologist*), and the Society for American Archaeology's newsletter, published positive examples of the cooperation between Native communities and archaeologists. In *Native Americans and Archaeologists: Stepping Stones to Common Ground*, produced by the Society for American Archaeology, the articles provide detailed examples of cooperative efforts. *Working Together: Native Americans and*

Archaeologists republished columns from the *SAA Bulletin* from 1993 to 1999. The edited book detailed both the cooperative efforts and tensions that still existed regarding the excavation of Native American sites and burial grounds.

One of the many positive results of NAGPRA is that it encouraged archaeologists to also evaluate the way they also worked with other non-Indian descendant communities. Archaeologists increasingly began to see community collaboration as a positive endeavor (Derry and Malloy 2003). The highly publicized excavation of the African American Burial Ground in New York City highlighted the involvement of the African American community in decisions regarding the preservation, protection, and public presentation of this site (LaRoche and Blakey 1997). Archaeologists became more receptive to presenting a multivocal history, to studying minority history, to incorporating oral history into their research, and to discussing their research agenda with members of the descendant community (Jameson 2004).

With the changing archaeological perspectives on outreach, community members were moving from the category of "research subjects" into "partners in outreach." Collaboration and partnership requires an ideological shift for archaeologists. The traditional academic or institutional hierarchy is gone – the "control" of the project is no longer solely in the hands of the archaeologists. In partnerships colleagues work together and respect each other. Each side has something to bring to the table and the goals of the project are decided jointly. The archaeologists also quickly learn that there are multiple voices within the community and those individuals do not always agree on goals, procedures, and end products for a project. Successful collaboration means opening up a dialogue, truly listening to each other, and exchanging ideas. For archaeologists, learning how to move away from a hierarchal model to a collaborative model was sometimes a slow process and difficult process. As archaeologists experimented with collaboration, sometimes a project began without community input, but as the project evolved, the insights, commentary, and suggestions from community members helped it to change over time. For other archaeologists undertaking participatory action research, the projects started with community partnerships and research agendas were decided jointly. During this time of experimentation, valuable lessons learned were learned from all of those diverse partnerships and the end products were greater than the parts (Shackel and Chambers 2004; Jameson and Baugher 2007). A growing number of archaeologists are becoming committed to community partnerships.

Challenges of Archaeological Education and Outreach

Archaeologists are involved in educational outreach in museum education, in CRM projects that present findings to the public through tours, exhibits, and lectures, and in publications written for the public. However, the rest of this entry is focused on innovative teaching approaches to outreach: (1) community service-learning classes for college-age students; (2) archaeological summer camps and school programs for high school, middle school, and elementary students; and (3) noncredit adult education programs in archaeological field and laboratory work. All are educational and involve partnerships with professionals in other disciplines, and they all promote community participation. Universities, museums, historical societies, and government agencies including municipal archaeology programs provide these programs.

Community Service-Learning for University Students

There has been a growing need in the profession for archaeologists to be trained in community service, public outreach, and ethics. Because of the numerous changes in the way archaeology is conducted, the Society for American Archaeology in their book, *Teaching Archaeology in the Twenty-first Century*, challenged archaeologists to rethink their approach to the teaching of archaeology and suggested the need to reform curriculum. Community service-learning is one of the reforms in archaeological education.

Service-learning is a North American higher education reform movement that combines community service with academic courses. Service-

learning is an educational pedagogy that had its roots in 1960s social activism in the United States. The Civil Rights movement motivated students toward community action and civic engagement. In the 1970s the students were involved in community-based internship programs. By the 1980s, college community service moved to a model where the outreach was part of academic courses.

Within the last decade of the twentieth century and the first decade of the twenty-first century, archaeologists started to experiment with service-learning courses (see articles in Nassaney and Levine 2009). Students in service-learning courses still learn traditional archaeological methods and theories. In addition, these courses address ethics, outreach, and community partnerships, link theory with practice, and encourage our students to become critical thinkers.

The field of service-learning contains diverse pedagogies and theories (Crews 2002). There is no one "right" methodology and archaeologists have employed diverse approaches to service-learning courses. Community service-learning can be the focus of an entire course or a component of a course. Incorporating service-learning into a field school is one method often used by archaeologists. Some large multiyear fieldwork-based community projects also have service-learning components linked to other classes, such as museum classes, or even introductory level classes. Faculty members can choose to have community outreach either as a required component for all students or as an option (see articles in Nassaney and Levine 2009) (Fig. 1).

The successful community partnerships are those that evolve over the years. With a multiyear project, there is time to develop a deeper understanding of the community and its history, time for the academic-community partnership to re-evaluate the original research questions, add new questions, revise the goals and the anticipated end products, and in the end accomplish a more detailed, mutually satisfying, community-based project (Baugher 2009). For example, for many decades there has been a tense relationship between Native Americans and archaeologists and slowly there have been efforts to build bridges through community-based projects (Colwell-Chanthaphonh and Ferguson 2008).

Some service-learning courses use participatory action research (PAR). In creating a research partnership with nonarchaeologists, archaeologists do not totally discard their own research questions when community members become involved. The research agendas are jointly decided. Community members can become involved in their own community history, assist in the research, and may come forward with information from family collections that provide unique additions to the research (Baugher 2009: 41). This work is now known as "engaged

Communicating Archaeology: Education, Ethics, and Community Outreach in North America,

research." These collaborative projects have generated research valued by both the archaeologists and the community, such as the long-term Fort St. Joseph Project in Niles, Michigan by Michael Nassaney and his students from Western Michigan University.

One of the unique university collaborations has been in Quebec City in Canada. Since 1982, the City Archaeology Program has partnered with Laval University (Moss 2017: 123). Perhaps their most famous outreach project has been a collaboration with the owners of the Auberge Saint-Antoine hotel in the Old Town Historic District. Archaeological field schools were run from 1992 to 1996. After the work was completed, the City Archaeologist and archaeologists from Laval University worked with the hotel's designers to integrate the rich archaeological heritage into the design of the building (Moss 2017: 125). William Moss describes the archaeological outreach:

> Each of the six floors in the complex is associated with a period and an historical figure linked to the site. Special artifact displays representing the appropriate period are placed in controlled-access portions of the hotel, such as elevators and room-block corridors; custom-designed furniture displays artefacts from the corresponding period in each room. (Moss 2017: 125).

Archaeologists and students from Laval University in partnership with the City Archaeology Program have also collaborated with other community partners to develop additional innovative public outreach programs (Moss 2017).

In service-learning courses, students may also face ethical issues. For example, some students are faced with the realization that as academics they do not have the "right to know" everything about another culture. They may discover that while they may want to research a topic, such as a religious rite, but the community may not want to discuss the religious practice with the student. For Cornell University students working with Cayuga and Tutelo Indians in Ithaca, New York, the protection and preservation of burial grounds became a very real issue, not an abstract scientific topic (Baugher and Frantz 2013: 119). Students who unconditionally supported the scientific excavation of cemeteries came to support Native Americans right to protect their ancestors' remains. In summary, some of the major educational benefits of service-learning courses are that students learn to communicate with people from diverse cultural and economic backgrounds, discover how to become both better "listeners" and better collaborators, and hopefully become more civic-minded and engaged citizens.

Archaeological Summer Field Programs for School-Aged Children

Archaeologists in the United States and Canada have partnered with educators to create innovative programs for high school and elementary school-aged children. North American archaeologists have created training programs that educate and inspire youth, involve community partnerships, develop an appreciation for cultural diversity, teach work ethics, and perhaps create the next generation of preservationists. But this was not always the case. Traditional archaeological work with youth has involved only college-aged students. With processual archaeology and the emphasis on scientific fieldwork, the use of noncollege-aged youth was regarded by some archaeologists as weakening a project and introducing a greater potential for errors in fieldwork. Other archaeologists believed that work with teenagers and children were a waste of time and provided no benefit to the profession. In the 1970s, Stuart Struever, then a professor at Northwestern University in Chicago, was an early pioneer in archaeological training for high school and middle school children. Struever's programs at the Center for American Archeology in Kampsville, Illinois, were connected to Northwestern University, which has a long tradition of encouraging students to learn outside the classroom. Struever's highly structured summer programs provided student training in the various components of field and lab work. Students were able to experience the diverse components of laboratory work in ethnobotany, faunal analysis, palynology, lithics, and ceramics (Struever and Holton 1979: 81–136). This program was innovative for the 1970s because it not only brought the scientific rigor of what Louis Binford called the "new

archaeology" to the excavations, but Struever also demonstrated that younger students could be trained in interdisciplinary, scientific archaeology. Struever inspired other archaeologists to experiment with programs for children and teenagers.

These early programs often focused on involving students in half-day or full day programs. Some archaeologists offered 1-week summer field programs. Students participated in excavations, which could involve work on a mock dig, excavation through backfill, or excavation through the mid-to-late twentieth-century levels of a site. Archaeologists quickly learned what National Park Interpreters have known for decades that children are not miniature adults (Tilden 2007). Archaeologists discovered they needed to learn more about theories of how children learn and children's attention spans (Lewis 2007: 306). In all the successful programs, archaeologists partnered with educators to insure that the program was age appropriate and that the archaeological material fit into the education curriculum. By the twenty-first century, many of the 1-day youth training programs shifted emphasis away from fieldwork and now include laboratory and library work, experiential work such as flint knapping and making pottery, classroom lecture/discussions, and visiting sites (see articles in Jameson 1997 and Jameson and Baugher 2007). Fieldwork opportunities are often limited to highly supervised excavations, usually as 1-week summer programs. Examples of some successful programs for children and teenagers can be found on websites for the Fort St. Joseph Children's Camp in Niles, Michigan, the collaborative archaeology camps offered by Ontario Heritage Trust and the Spadina Museum in Toronto, the Suffolk County Archaeological Society's children's programs on Long Island, New York, and the Community Archaeology Program at Binghamton University in Binghamton, New York. These four successful programs have been operating for decades.

While archaeology rarely appears in state or provincial educational requirements, archaeologists have partnered with educators to bring archaeology into the classroom. The Society for American Archaeology, the Canadian Archaeological Association, and the American Institute of Archaeology all have information on their websites on how to incorporate archaeology into lessons for the elementary school classroom. Short paperback books written specifically for middle school or high school students bring archaeological discoveries to a younger audience. In North American public schools, archaeology can fit into both the social studies curriculum and in science education with its inquiry-based instruction. The successful programs all work because archaeologists design the programs in collaboration with teachers (see articles by Jeppson and Brauer, and Stone in Jameson and Baugher 2007). The programs are age-appropriate and also meet government mandated science and social studies curriculum requirements. Successful programs for children are enjoyable and fun as well as educational (see articles by Doroszenko, Ellick, and Stone in Jameson and Baugher 2007) (Fig. 2).

Archaeologists collaborated with teachers in art, communications, industrial arts, and social studies. Students were introduced to archaeology, preservation, and local history. The successful programs taught concepts of stewardship and ethical behavior in the field and demonstrated the roles the students could play in protecting and interpreting their community's history.

Adult Education

Teaching also involves innovative educational (noncourse credit) programs for adults. These programs not only teach field and lab methods, but also ethical practices. Some archaeologists were opposed to adult training programs because they feared that adults armed with a better understanding of archaeology would become looters. However, archaeologists directing adult training programs have found the opposite to be true – adult participants become grass roots preservationists NOT looters (Cressey et al. in Derry and Malloy 2003; Versaggi 2007). In the 1970s, Stuart Struever with Northwestern University and the Center for American Archaeology offered archaeology summer field and laboratory programs for adults. While no longer affiliated with Northwestern University, the Center for American Archaeology still offers noncredit adult archaeology programs.

In 1996, the Public Archaeology Facility (PAF), a research center at Binghamton University (State University of New York), established the Community Archaeology Program (CAP) and the program is still active after more than 20 years. The 4-day CAP training program is for adults and the participants include local teachers as well as interested community members. Some of the graduates of the CAP program return to volunteer on other PAF projects. The archaeologists have found that some CAP participants have become active preservationists who have lobbied to protect and preserve local sites (Versaggi 2007).

Adult programs are not just run by academics. Some of the very successful programs are in the domain of municipal archaeology programs. In 1977, archaeologist Pamela Cressey, through the City Archaeology Program in Alexandria, Virginia, established a program to train adults in field and lab methods and incorporate the trained public in her urban excavations (see Cressey et al. in Derry and Malloy 2003). The Alexandria Archaeology Program not only trains adults in archaeology but also learns from these community members. The community members are from many different professional, economic, and ethnic backgrounds and this interdisciplinary community team work in partnership with the archaeologists on excavations, exhibits, and the preservation of Alexandria's heritage (see Cressey et al. in Derry and Malloy 2003). The core of long-time volunteers makes up the majority of the staff for the City Archaeology Program's projects with a few full-time City Archaeologists directing the volunteer staff. One of their best-known projects was a community-initiated collaboration with the Friends of the Freedmen's Cemetery to preserve the cemetery buried underneath contemporary buildings. After the City of Alexandria purchased the properties and demolished the structures, the City Archaeologists and adult volunteer staff excavated the site and located 631 burials (Bromberg et al. 2017: 216–218). Respecting the wishes of the descendant community they did not excavate any bodies. In 2014, the city dedicated a memorial park to the Freedmen's Cemetery with a flat stone placed on each of the 631 graves, a remembrance wall listing the names of the deceased, and a large stone sculpture as the centerpiece of the site (Bromberg et al. 2017: 217–218).

Boston also has a very active adult education program, similar to the one in Alexandria, Virginia. Since the 1980s the Boston City Archaeologist has worked with a core of trained adult volunteers to excavate sites that face development but do not trigger environmental reviews and legally mandated archaeology (Bagley 2017).

More archaeological adult education training programs appear each year as archaeologists realize that an informed public will be the best partners for the preservation of heritage sites. Some state and provincial archaeological societies are engaging and training avocational archaeologists to work in partnership with professional archaeologists in both excavation projects and preservation efforts. Some nonprofit private organizations in both Canada and the United States provide field

and lab training for adults, and some of the adults end up providing much need volunteer labor on community excavations. Some examples of these collaborative projects are: the Fort St. Joseph Life Long Learners Program in Niles, Michigan, Crow Canyon Archaeological Center in Cortez, Colorado and the Artefactuel Program in Quebec City, Quebec. Community members bring to the project their unique knowledge of the community and contribute to the recording of community oral history. In the adult training programs, archaeologists have found that by involving community members in their own heritage that you help create grass roots preservationists (Versaggi 2007).

Conclusion and Future Directions

The challenge facing archaeologists is to move out of a hierarchal system that separates the archaeologist from the community and continues this privileged view that the archaeologist knows what is best for the public. It also involves giving up control and power because in community collaborations there are joint decisions. Partnership is a key component to a successful educational outreach project. The idea is for everyone to learn from each other. In working in collaboration with community partners, archaeologists combine their experience, background, and professional skills with the skills and knowledge of their community collaborators to create a successful project. Successful outreach results whenever all parties are willing to learn from one another, where there is respect and dialogue, where there is a sharing of responsibility and shared control of the project – in other words – where there is an equal partnership.

The other challenge is that it is time consuming to design and run field and lab programs for adults and children. However, archaeologists need to see the long-term benefits in creating programs for the public. Our current political climate is increasingly becoming antipreservation and pro-development. Therefore, archaeologists must create allies and supporters outside our profession. As we reach out and engage a wider audience, grass roots support for preservation and archaeology will grow.

Community and Archaeology

Luis Gerardo Franco
Independent Researcher Antropólogo. PHd en Ciencias Humanas con mención en Estudios socioculturales, Universidad Nal. de Catamarca, Argentina, Piendamó (Cauca), Colombia

State of Knowledge and Current Debates

For at least two decades, the conjunction between Community and Archaeology has gained prominence in major disciplinary debates, contributing to generate new theoretical and methodological contributions, as well as new approaches to the role of Archaeology in relation to human beings and with the social contexts where its practice is developed. This conjunction is the product of a series of changes within the discipline that made it possible to open up new academic positions. Such changes, it should be clearly stated, have a much greater dimension, since they were not exclusive or originated in archaeology, as they are part of the transformations of subjectivity and human experience in the historical moment from modernity to postmodernity (Harvey 2008; Lyotard 1995) or submodernity (Auge 2000). It is precisely in this transformation that the words/concepts of Community and Archaeology begin to describe a new type of practice within the discipline from where these must be read and understood, configuring the discursive field for the appearance of the so-called Community Archaeology. To deepen this appreciation, it is necessary to develop a course of action that embodies the connotations of the two words/concepts in question: Community and Archaeology. And only then, we could get closer to some of the key issues that they display on the scene and that articulate Community with archaeology. It is important to highlight that this entry tries to provide a context of discussion for the issue in question and because the bibliography, both in relation to the thoughts of the Community and the connections that Archaeology has with it, is increasing, and it would be impossible to fully account for all the discussions. For this reason, some ideas and authors have been chosen to allow generating a general understanding on the subject.

In general, all social disciplines have tried from their start, to understand all aspects of human beings' social life: forms of sociability, change, economic and thought systems, intergroup relations, historical trajectories, and their symbolism, among others. Each discipline in delineating its object of study and its research methods was differentiating and building a corpus of knowledge about the aspects in which human beings' life was divided. These aspects can be summarized in the great social, political, and economic

fields, structuring fields of Political Science, Economics, Sociology, and History, as well as everything outside the West that was structured by means of the Anthropology and Oriental Studies (Wallerstein et al. 1999). Archaeology, depending on which side of the Atlantic you look at, has been connected to History or Anthropology. However, it has shared the concern of understanding the dynamics of human societies in the past. This interest has led it to adopt and combine both methodological and theoretical positions from different disciplinary fields: History, Anthropology, Sociology, Biology, Geology, and Philosophy, among others. Archaeology interdisciplinary nature has made it possible to assemble a very rich and diverse conceptual baggage, as well as giving it the possibility of intervening in increasingly wider social contexts that are not limited to the distant past. Likewise, the debate has been enriched because the dialogue with other disciplines has enabled questioning assumptions previously held as law, such as those referring to radical separations between material/immaterial, subject/object, and past/present.

Thus, the introduction of concepts in archaeological practice opens up doors to new paths, some of them, unexpected. This is the case of the word/concept: community. It is found regularly in many archaeology books and articles but as we find it in many texts, its use is often given as a word that fulfils the function of describing some organizational moment of human groups. So it is not uncommon to find it being interchangeable or functioning as a synonym of society, collectives, or groups. In Raymond Williams's classic book *Keywords: A Vocabulary of Culture and Society*, he pointed out five meanings for community that show its trajectory: the first use is located between the fourteenth and seventeenth centuries and made reference to "the commons or common people, as distinguished from those of rank"; the second sense is used from the ninth century onward and it refers to "a state or organized society, in its later uses relatively small"; the third sense is used since the eighteenth century and refers to "the people of a district"; besides, the fourth sense becomes effective since the sixteenth century and alludes to "the quality of holding something in common, as in community of interests, community of goods"; and finally, the fifth sense, also in use since the sixteenth century, refers to "a sense of common identity and characteristics" (Williams 2003: 76). Williams, in turn, points out that Community since the seventeenth century took on special importance and was thought of as a more immediate form than society. Such a sense of immediacy or locality was accentuated since the nineteenth century in the context of industrial societies. In the same century, the contrast between more direct and meaningful relationships of the community and more formal and instrumental relations of society is emphasized (Williams 2003). Thus, from this moment on, the community, in the classical sociological tradition, has been thought of in a dichotomous and temporal relationship with society since they were thought of in an oppositional relationship and in a sequence that begins with the community and then becomes the society. This way of setting out this dichotomous and temporal relationship has as a background the idea, also based on the tradition/modernity dichotomy, that modern society devastated community bonds.

Leaving the Community Behind

Ferdinand Tonnies (2001 [1887]) defined the meaning of each concept in a systematic way. He characterized the type of relationship and bond that was established within the social groups, and thus he was delineating the essence of the Community, in which, according to Tonnies, the relationship and the social bond derived from it can be conceived as a real organic life, opposed to Society, which establishes its relationship and social ties as a purely mechanical construction (2001: 17). "*Gesellschaft* means life in the public sphere, in the outside world. In *Gemeinschaft* we are united from the moment of our birth with our own folk for better or for worse. We go out into *Gesellschaft* as if into a foreign land" (2001: 18). This way of thinking about the community is connected to European

Romanticism, which "consecrated the human community as a suprapersonal force and an intramundane demiurge, which provided a source of historical legitimacy and sense, establishing itself in the secular reality that supplanted the transcendental God" (Gonzalez Requena 2010: 68). The community sense comes, then, from an inner nature, something organic installed in our being. It is for this reason that the sociology of the late nineteenth century and much of the twentieth century has thought of the community as something different from society, even in opposition.

The second half of the nineteenth century was a time of great political, economic, and social transformations in Western Europe. In this context, a social organization based on the liberal principles of individualism and reason combined with an increasingly expansive capitalist system and with the consolidation of nation-states is firmly established. These elements, in short, from a romantic view, were the cause of the dissolution of the bonds of belonging as well as the community values that gave place to the emergence of the individual, in abstract terms, who had to face the disenchantment of the world, as Weber would say, with the then reigning power of reason. Thus, the new political structures, the consolidation of capitalism as a planetary economic form, the rationalization of social life, and the emerging consolidation of scientific thought generated, on the one hand, the condition of uncertainty of the modern individual who no longer had a stable handhold for his identity and future and, on the other, the emergence of a new structure of significance that sought to generate bonds between the heterogeneity of existing individuals within territorial borders: the nation-state. This construction sought to form the solid base for those rootless individuals creating stability in the face of the great transformations of the time.

The passage from tradition to modernity can be read through Tonnies' conceptualization of Community and Society. For him Community "means genuine, enduring life together, whereas Society is a transient and superficial thing. Thus *Gemeinschaft* must be understood as a living organism in its own right, while *Gesellschaft* is a mechanical aggregate and artefact" (2001: 19). Other sociologists interested in the forms of the social relationship have noted this same mutation in other terms: Weber, in *Economy and Society*, thinks of a type of relationship based on a subjective feeling of common belonging and another based on interests motivated by reason and oriented to objectives. Durkheim (1985), in turn, opposes an organic to a mechanical solidarity. These oppositions to social relation forms seem to be overcome due to the belief that the modern erased all traces of tradition. At present, we all know that this was not the case. What should be highlighted is that this kind of thinking about social relations and forms of grouping are framed within a nostalgic context. As Fistetti (2004) points out, it should be noticed that Tonnies, above all, was a critic of capitalist "society," and in this sense, he expresses, analogous to Marx's critique, a desire or a "need for a community" (Fistetti 2004: 137). "Sometimes a romantic wish for a supposedly lost community, and at other times, no less frequent, a wish for a future community, for a "community" that is announced *later* and not *before* the "society" (Álvaro 2010: 10). Marinis (2005: 7) summarizes sociology's concern at the end of the nineteenth and early twentieth century about these forms of social relationship: "if in the community there was an order and there were solid and stable identity guarantees for its members, in society both things could be diluted."

The dissolution of an old order, solid and stable, gives rise to the configuration of a new one in which "everything solid vanishes in the air" (Berman 1989). For example, Bauman (2004) thought about the situations of social relations in modernity and defined those using liquid metaphors: liquid modernity, liquid love, etc. In these swampy fields, the modern subject, already disenchanted with the world, and in consequence, isolated from the community, will try to find security. Thus, the foundation of reason, a principle of individuality, and the abstraction of the world are the preconditions that inaugurate the new social order in the field of subjectivities. The modern episteme, described and located by

Foucault in the eighteenth century, is a sort of consolidation of that Cartesian subjectivity that privileges reason and consolidates modern subjectivity. It is, then, through reasoning that truth is achieved, principle of the modern rational conception that permeates all the scientific discourse until the present. The Cartesian subject, therefore, was configured as a subject capable, through reason, of knowing the world and knowing himself without mediations other than himself. This idea of a cognoscent subject, detached from the will of a supreme God, would guarantee the positioning and dominion over nature (external and internal) through technique-instrumental reason.

Both at the level of modern science and individual subjectivities, the idea of the modern subject implies certain categories that assure stability because they give it a pre-established framework, a priori, to grasp and relate to the world from a privileged position. These are Kant's transcendental categories with which the ontological sustenance of the experience of the modern subject is consolidated. Through this consolidation, an ontological, and therefore essential, superiority is declared, which fixes this subject at the top of a hierarchical scale. Such categories ride on the Western experience until the present, colonizing other realities. In this sense, the constitution of discursive training fields, such as archaeology at the end of the nineteenth century, and the constitution of subjects connected to such fields are inscribed in the processes of subjectivization proper to modernity. Berman says (1989: 13–14):

> To be modern is to live a life of paradox and contradiction. It is to be overpowered by the immense bureaucratic organizations that have the power to control, and often destroy all communities, values, lives; and yet, do not hesitate in our determination to face these forces, to fight to change their world and make it our own. It is to be both revolutionary and conservative: alive to new possibilities for experience and adventure, frightened by the nihilistic depths to which so many modern adventures lead, longing to create and to hold on to something real even as everything melts.

The nation is one of those modern adventures that sought to make sense of individual life by creating "imagined communities" (Anderson 1991) to bestow existence with meaning, to that mechanical aggregate Tonnies referred to as society. In this process, archaeology played an important role. According to Gnecco (2012: 94–95):

> Archaeology was related to the nation states through the creation of the national identity. It provided the temporal depth and unified symbolism upon which modern society was preached about. It gave the nation the necessary continuity so that it would not appear as the naked transgression of what it had replaced. The *new* (modernity, State-nation, national society) found in the *archaeological* (discourses on antiquities and ancestors based on objects) a profound density. What does it mean to be national in archaeological terms? It means modernizing the way of accounting time, making it transcendent (objective, neutral), bringing a collective (the national society) and a singularity (the modern individual) to recognize each other as a whole and part and unite them in a ceremonial, mnemonic space.

Gnecco's description of the role of archaeology in the formation of nation-states has been staged, with its various peculiarities, since the 1990s, without any doubt, in all countries where archaeology has been established as discipline (Diaz-Andreu and Champion 1996; Gnecco 1999; Kohl 1998; Kohl and Fawcett 1995). Thus, archaeology built the past of societies that were projected into the future. In general, this was done adopting evolutionary assumptions that indicated the succession of states until their culmination in Western civilization, now expressed more strongly in the principles of modernity. In this sense, as indicated by Almudena (2015: 28), the discourse of Archaeology, from its initial developments in the nineteenth century to more than half of the twentieth century, offered the scientific justification for ordering human groups from savagery to the civilization, order that corresponds to other historical transitions indicated in various social disciplines such as tradition/modernity or the one we are interested in here, that of the community to society. For the latter, the state of savagery would be associated with the forms of community organization, while civilization would be organized as societies with specific characteristics such as bureaucratization, hierarchies, and

surplus economies, among others. Not in vain, archaeology sought as the origin of nations societies that fulfilled the features of modern society.

The modern origin of Archaeology and its connections to the formation of nation-states and nationalisms accentuated the principles of individualism and progress in the discipline and helped to root them into the common sense of society. This historical moment was directed by a paradigm of homogenization. The example of ethnic minorities is one of the most evident examples of modern project's homogenizing pretensions. The idea in general was to uproot the human beings belonging to these minorities to incorporate them into the social body as free and autonomous citizens in their exercise of reason. This idea was materialized in different parts of the world through various strategies: territorial displacements, educational policies, and extermination of entire ethnic minorities, among others. The others of the nation-state were forced out from the community to be incorporated to the citizenship. This implied an abandonment of their own cultures (language, beliefs, and customs) to begin to share the elements of the majority of the society: to speak the dominant language and enter the literate education system and participate in market relations, among other things. This was part of the accentuated interest of modern discourse to individualism and the individualization of subjects within society in general. In short, modernity privileged a form of association that was oriented by the logic of reason and individualism; it sought to dissolve the bonds of human beings with local communities to replace them with the homogeneity of the national society. In this context, archaeology did not speak or relate in terms of explicit discursive production with communities, since it was directed toward the production of scientific knowledge. In turn, it provided vital elements that complemented the role of the nation-state as an element of social cohesion to the detriment of local association forms more connected to the idea of the community indicated at the beginning of this section. However, the last decades of the twentieth century witnessed social, political, and economic transformations that would reactivate the sense and the search for the community by witnessing the strength of the State's social cohesion weakened within the framework of neoliberal policies.

Community Resurgence

The transformation in the discourse of modernity supposed a political, economic, social, and cultural reorganization. This was due to the crisis of the nation-state in the 1970s and was basically due to the impossibility of maintaining an idea of a culturally homogeneous nation, promoted mainly by the visibility of human groups that had previously been marginalized and made invisible and even included as belonging to the same national culture. This crisis was also due to the states' loss of sovereignty in connection with politics and economics. The failure of the modern nation-state, particularly the nation, was due to the fact that the objective differences of culture and identity between the different groups within it prevented the construction of a national identity. In this sense, in the nation-state, according to Bauman (2006: 28), the permanent invitation (to assimilation) was represented as a sign of tolerance. In fact, the supply of assimilation derived its sense from the rigidity of the discriminatory norms, from the purpose of the inferiority verdict issued to the values that did not comply with the norm. Tolerance, conceived as a stimulus to the adoption of "progressive attitudes," expressed in the search for individual "improvement," made sense as long as progress measures were not negotiable. Within the assimilation policies, the tolerance exercised onto individuals was closely linked to intolerance toward collectives, values, and, above all, their powers to legitimize values. However, with the discursive change of modernity, a new tolerance arises: multicultural tolerance.

In the organization of the social, from the late 1970s and early 1980s, multicultural policies began to be established. Multiculturalism posed the coexistence of several cultures. Multicultural countries are therefore characterized by the acknowledgment of this coexistence and recognition of very diverse groups different from the

majority national group: ethnic and cultural minorities, gender, etc. This was a great transformation not only in terms of the conception and organization of the State but also in terms of the politics of identity. In this sense, identities ceased to be understood as fixed and immutable entities and became fluid identities always in the process of construction, and also, positional. Likewise, aspects that point to the relations of power and domination emerged in countries of the so-called third world, in terms of the colonial order, to constitute identities, particularly subaltern identities. These transformations in the field of the subject conception and identities also obey political issues related to the decline or erosion of the nation-state already mentioned. As Hall (1997: 44) has argued: "through the erosion and instability of the nation-state, of the self-sufficiency of national economies and, consequently, of national identities as points of reference, there has simultaneously been a fragmentation and erosion of collective social identity." Such conditions have been fostering for the emergence of new forms of sociability and association as well as the reemergence of different types of collectives throughout the world, which had been made invisible and/or subalternized by the identity policies of the modernity.

However, this emergence, and reemergence, of collective identities, which in many cases made reference to community or neo-community discourses, has been read from some perspectives of social disciplines not as liberation from every yoke imposed by the nation-state and/or capital but as a rearticulation of new forms of control and domination. Hence there has been a proliferation of the community in different places: governmental, nongovernmental, social movements, business sectors, and academics, among others. However, the reemergence of the community is related to a diverse experience linked to local territorial spheres but with associations and extra-local and global projections, making a broad contrast with the idea of national spaces. It is worth briefly mentioning the case of multiculturalism policies, which sought to create a paradise of harmony and coexistence of cultural diversity. And little by little, the non-compliance with their task and the number of problems that it carried out would be uncovered. In this regard, the Slovenian philosopher Slavoj Zizek clearly pointed out the existence of an intimate relationship between multiculturalism and global capitalism; moreover, he also helped to uncover the hidden faces of multiculturalism by saying that: "multiculturalism is a form of racism that is denied, inverted, self-referential, a 'racism with a distance': it respects the identity of the other, and conceives of it as an authentic closed community towards which the multiculturalist maintains a distance that is made possible thanks to his or her privileged universal position"(Zizek: 2003; 172).

Raymond Williams (2003: 77) pointed out that unlike the other terms referring to social organization, community never seems to be used unfavorably or to have as a contrast any positive term of opposition or distinction. In turn, Bauman (2006) says that beyond the meaning of the word Community, this is one of those few words that produce a feeling, and much more, a good feeling. In times of uncertainty, there is nothing like feeling the security of a warm, cozy, and comfortable place like the community (Bauman 2006: V). The search for that good sensation, that "lost paradise," was one of the answers to the reconfiguration of labor markets, the creation of new capital markets, the emergence of new subjectivities, and the blurring of political and academic borders. This indicates a contents' breakdown with earlier times. However, as suggested by Jameson (2002: 35) "the radical breaks between periods do not involve complete changes of content but rather the restructuring of a certain number of elements already given: traits that at a previous period or system were subordinated now become dominant, and others that had been dominant become secondary."

Thus, the reorganization of Western societies witnessed the emergence of complex frameworks between the flows of an increasingly present and incisive globalization and a diverse range of local responses. In the social field, global fragmentation implied a visibility and, therefore, a proliferation of interpretations of the world around the past,

present, and future of human beings, both individually and collectively. This situation has as a consequence the reemergence of concepts that had been or banished from social thought or had reduced their heuristic capacity for the interpretation of reality: example of them is the concept of multitude (Hart and Negri 2004) and, the one that interests us here, that of community (Agamben 1996; Esposito 2003, 2009; Nancy 2001, 2007). Even new concepts have come to be put forward for these new forms of sociability and association; this is the case of the concept "assembly" developed by Latour (2008) within the actor-network theory. In the case of archaeology, the concept of "entangled" proposed by Ian Hodder (2012) can be seen to express the dependencies between the social and the material world, almost in the manner of human communities and things.

The community has become a necessity in a present lacking a sense of roots. For this reason, it is promoted from all sectors. However, promotion can easily become regulation, and therefore denial of autonomy and freedom. The latter are vital elements in all community projects. The last two decades of the twentieth century and the first of the twenty-first century have witnessed a renewed interest in the human and social sciences for the theme of the community. In the field of archaeology, influenced by the global context, these transformations implied a rereading of its epistemological and ontological bases leading to the development of new approaches with interpretative strategies different from those already tested up to that moment. At the same time, and due to the empowerment of indigenous and Afro communities and other local communities that faced the "traditional" archaeological discourse as a colonialist discourse, archaeology was challenged to take a position in the different scenarios where the past was no longer that placid place that the archaeologists visited in their excavations and that they reconstructed in their texts but a territory in dispute where struggles were fought on territorial rights, autonomy, and identity. However, it has been pointed out that changes in discipline in the multicultural era have confronted what could be one of the most important and paradoxical questions of contemporary archaeology: one that says that "archaeology has entered politics to remain strictly out of it" (Gnecco 2017: 83). A kind of change so nothing changes. The opening and inclusion of other ways and visions to understand the past and the proliferation of archaeologies is its condition of possibility today and in turn is the way to rearticulate each of these "alternatives" to the canon of disciplinary control.

The Community in Community Archaeology

At present, the archaeology agenda includes issues that were once unacceptable in the disciplinary discussion. The participation of local communities in archaeology is due to an opening in the disciplinary field and to the reconfiguration of the social space at the end of the twentieth century. In the field of archaeology, such reconfiguration opened the doors to an archaeological practice and a more inclusive version of the past. In this context, discourse on the community has become a practice that can act as a counterhegemonic strategy or as a spearhead for state and/or capitalist policies. This is the case, for example, of Contract Archaeology, as it is known in Latin America, or of the Archaeological Resource Management (ARM), as they are known in the USA or Europe, where the discourse of the community has been incorporated in order to make high economic impact projects viable and thus to avoid problems with its execution, as Demas (2002: 32) assures, it is more unlikely that people will object to a project in which they have participated in its planning. In this way, interest in the community appears as a capitalist strategy to achieve intervention and exploitation of territories absent from colonial/capitalist cartography. The current discussions about mining and hydrocarbon multinationals and their relationship with local communities, and the intervention of archaeology as a mediator, is a good example of this situation.

However, many who practice community or in-community archaeology have a more positive

view pointing out that it transforms the nature of the discipline in fundamental ways (Marshall 2002: 215). In general, the work on archaeology and community is thought as oriented to citizen participation related to a democratic expansion, both socially and academically, and in the peoples' self-determination. They are strategic moves for a more equitable and egalitarian society. The *Journal of Community Archaeology & Heritage* is a good space to have a panorama of the diversity of themes and places community archaeology works with. This Journal, since its creation in 2014, tries to gather the experiences learned from more than a decade of development of community archaeology and the opportunities it opened for the discipline as pointed out by Yvonne Marshall in her famous text in World Archaeology dedicated to community archaeology. There Marshall says (2002: 218):

> Community archaeology represents an opportunity. We need it, not because it is politically correct, but because it enriches our discipline. Community archaeology encourages us to ask questions of the past we would not consider, to see archaeological remains in new light and to think in new ways about how the past informs the present.

Designing a field of more horizontal relationships between Archaeology and the communities is the interest of all the undertakings of this type of practice, which has tried to establish an autonomous approach generating their own methods and theories and staging them in different projects to world level (see Silverman 2011; Simpson 2010; Tully 2007). For example, Tully (2007) argues that community archaeology seeks to diversify the voices in the interpretation of the past and its objective is to facilitate collaboration in all research phases and it plays an important role in the subsequent presentation of research results. There is a firm commitment in this practice to recompose some of the damages committed by archaeology throughout its history, the lack of inclusion, the prevalence of a monological discourse, and the political detachment. There is an alternative known as inclusive archaeology, which covers the diverse voices about the past and which is committed to its social and political context. This attitude is not a novelty of community archaeology, but it tries to take these assumptions and consolidate "a multicultural conversation space" (Thomas et al. 2014: 2), as pointed out by the editors of the *Journal of Community Archaeology & Heritage*, thought and created to "provide a place where 'academic' voices and other voices participate in the same playing field" (Thomas et al. 2014: 2).

Some criticisms about community archaeology that have to do with the centrality given to archaeology in the relationship with the community have been pointed out (Moshenska 2008). Here the community often appears as a passive agent and being subjected to a kind of condescension and where power relations are disguised because, among other things, many of the community archaeology projects are developed in developing countries by archaeologists from the developed world. From another perspective, this turn of archaeology toward the community obeys to a strategy of change so that the order of things remains the same (a change so that nothing changes). This is Cristóbal Gnecco's criticism (2017) on the so-called alternative archaeologies. It is also possible to point out the privilege of the Western perspective in the conception of the community and its relationship with it; this privilege becomes evident when, for example, Tully (2007: 158) says that the inclusion of diverse voices by community archaeology does not compromise the scientific nature of archaeology. This situation is due to the fact that Archaeology is still protected by the objectivist idea of scientific discourse and continues to maintain the otherness in the outside, unleashing or consolidating with this what Esposito (2009: 88) calls the perversion of the idea of community, the one that raises walls instead of knocking them down.

A critical review of archaeology thought about the Community, both classical and contemporary thought, would confront it to unexpected situations that would force it to decentralize its perspective. This is due to the fact that the community confronts us with the opening, sharing, and dislocation of the being in common, which enable the appearance and interpellation between

the singular ones, which precisely are exposed in the suspense of the community, in the spacing and exteriority of the co-being (González Requena 2010: 82–83). The exposure of the co-being is not a natural knotting as you may think, it is rather a commitment that puts us in front of the other that constitutes us and before which we are due to. In this perspective, archaeology is no longer related only to the community, but it may be willing to interact with extended communities.

Community Extended and Archaeology

More local conceptions about the community refer to what could be called an enlarged or altered community. That is to say, that such a community does not belong exclusively to human beings. This situation is evident in human groups from all continents. In it, sociability exceeds the relationships between humans and installs itself in the realm of human/non-human relations. According to Grosso (2016: 20):

> "The extended community or the *altered* community is the community that is neither circumscribed sociologically nor anthropocentrically, and that, therefore, puts in tension a new thought of the political, because in those *community socialities*, non-human beings, the dead along with the living, hills, stones, water also intervene. . ."

In this sense, the conception of community, in Western terms, is limiting and does not express to be-in-common with all the beings of the world. The enlarged community calls life in constituent relationships. But at the same time, it maintains the values of freedom and autonomy, as well as its goals of the indigenous peoples' historical struggle and the recognition of the other.

In this conception a being-in-common is contained that is due to the other. It is a condensation of a responsibility toward the interior of the community as well as toward the exterior. Archaeology, from this perspective, is seen as a way to weaving ties with the ancestors, with the earth, with the historical struggles, and with the future-to-come of a society that seeks territories of existence where intercultural identities and policies are reproduced. It is well known that in this project archaeology must be transformed. Moving away from the disciplinary place that has driven it to pretend to be absent in the social relationships that shape the social contexts that are, in turn, its condition of possibility. Archaeology must become in relation, in coexistence, with the world. With that extended community that interacts not only with their human equals but also with nonhumans. The move, then, implies epistemological as well as political movements, which begin modifying their condition of exteriority in the social world. It is no longer *about* or with, but rather it is a *from* (Haber 2010). It is not *about* the community, but *from* the community. Thus, community archaeology will prove to be a transformative experience for all parties involved and not just instrumentalizing the spirit of the community that runs through our time, a time of ephemeral senses and fluid positioning. Finally, the conjunction of Community and Archaeology has not to be limited to a change of discipline; it has to have a much more ambitious commitment, that of transforming society.

Community Archaeology

Carol McDavid
The Community Archaeology Research Institute, Inc, Houston, TX, USA
Rice University, Houston, TX, USA

Introduction

This entry will provide an overview of "community archaeology" as it is practiced at the date of this writing (2012). Before narrowing the discussion to that topic, however, it is necessary to situate it within a somewhat broader frame – that of "public archaeology." The terms do not mean the same thing, even though they are often conflated. Even though the term "public archaeology" is discussed elsewhere in this volume, it needs to be touched on here in order to situate this entry. The position here is that public archaeology is a larger area of archaeological practice within which "community archaeology" operates (a particular variant of community archaeology that has emerged in the United Kingdom will be explored later in this entry).

In general terms, public archaeology can be seen as *any* endeavor in which archaeologists interact with the public *and* any research (theoretical or practical) that examines or analyses the public dimensions of doing archaeology. Therefore public archaeologists work in a variety of fields, including (but not limited to) heritage management, museums, education, curriculum development, the academy, journalism, tourism, commercial contract archaeology, and new technologies. Through both research and practice, they attempt to understand the political, social, and economic contexts in which archaeology is undertaken; the attitudes of disempowered and indigenous peoples toward archaeology; the educational and public roles of the discipline; the public perceptions of archaeology; how pasts are created and used; and the conflicts between academic and popular views of the past. In short, public archaeology is where information about the past, gathered by and sometimes for people in the present, is used by contemporary people for contemporary agendas and needs.

Definition

Community archaeology is, therefore, public archaeology situated in specific communities, populated by contemporary people within these communities. These communities are usually organized around a variety of overlapping and often fluid interests – family, descendant, ethnic, geographic, intellectual, political, cultural, and more. Therefore, community archaeologists attempt to understand these community interests and to incorporate them into their archaeological work in various ways. Not all public archaeologists are community archaeologists, but all community archaeologists do public archaeology.

Historical Background

The historical background of community archaeology emerged from the larger field of public

archaeology so, again, needs to be described in that context. Within Americanist anthropological archaeology, the term "public archaeology" was, until the early 1990s, usually defined as the commercial field of Cultural Resource Management (CRM), although it also included governmental programs such as the Federal Archaeology Program. This definition originally sprang from the reality that CRM archaeological projects were (and are) funded by the public purse and/or mandated by public legislation. Therefore, public archaeology work during this period included archaeology practiced on public lands (such as national parks) as well as archaeology conducted on native (tribal) lands.

It is important to note that during the beginning days of CRM, despite the widespread use of the term "public archaeology," there was little "public" input into in the archaeological work *itself* (McGimsey 1972). Part of the reason why (obviously this discussion glosses things a great deal) was that archaeological practice was dominated by those who advocated scientific methods as the best, if not only, way to do archaeology. Much has been written about this, but the main point is that this view did not allow much in the way of indigenous (or descendant or community) input as archaeological sites were being interpreted. During this period, most work with publics, when it did happen, was overtly educational (e.g., Smardz 2000). In addition, its primary aim was to convince the non-archaeological public that saving archaeological sites was important – that is, it was aimed at "stewardship." It was not aimed at involving the public in making decisions about archaeological sites or at including stakeholder communities in the ways archaeological sites were scientifically (or publicly) interpreted.

Changes in this view, with respect to community/stakeholder input into archaeological research, began to be explored by many archaeologists in the 1980s/early 1990s (see "Further Reading" for several examples). The most momentous early benchmark for discipline-wide change (in the United States) came in 1990, with the passage of NAGPRA (the Native American Graves Protection and Repatriation Act). This law gave indigenous Americans some measure of control over archaeological remains on tribal lands. The law was limited in many ways, but the key point here is that during this period the meaning of the word "public" in "public archaeology" began to shift and began to include living *publics* – and therefore living communities. Archaeologists working on native lands were, from that point, forced to take the opinions of descendant communities into account – and their methods and interpretations began, slowly, to reflect this. One major feature (some would say shortcoming) of NAGRA was the definition of "descendants" as documented, lineal descendants, and this limitation continues to create challenges for Indian groups which are unrecognized as such by the federal government (for one example, see Handsman and Richmond 1995). In addition, NAGPRA did not (and does not) apply to other descendant community contexts – such as historical archaeology on sites occupied by non-Indian, but also disempowered, cultural groups.

Even so, NAGPRA did drive important discipline-wide cultural changes, and the next major milestone in US public, and community, archaeology emerged within historical archaeology. This occurred in 1991 when, during a CRM archaeology project being conducted prior to the construction of a new federal office building in New York City, workers discovered the bones of more than 400 free and enslaved Africans and African Americans. The public uproar over these remains, and the public debate about how to excavate and interpret them, continued into the next decade and established new understandings of the words "descendant" and "community" within archaeology. Despite the lack of legislative mandate, the *cultural* descendants of those buried at what came to be called the African Burial Ground were successful in gaining control over how their ancestors' remains were excavated and interpreted (LaRoche and Blakey 1997). African American *communities* in New York City thus began key changes in historical archaeology, just as Indian groups had done the same thing in prehistoric archaeology.

There is still no NAGPRA for non-Indian lands, but the ethos that drove NAGPRA, and emerged from it, is now commonplace in many

archaeology projects across the United States. There is, however, a major exception to this rather broad statement: most archaeology (about 80 %) is still done in a CRM context (Neumann and Sanford 2001), which is driven by commercial agendas and motivations. It remains to be seen how, or if, meaningful community input (and by that I mean what might be called grassroots input, not corporate input) into CRM archaeology can ever happen.

In any event, as this has been happening in the USA, similar shifts have been occurring elsewhere, and a variety of postcolonial and global justice movements have played important roles in how archaeology, and community archaeology, is framed today. A major milestone in the global arena was the 1986 founding of the World Archaeology Congress, in part as a response to apartheid. Over the last two decades, there have been key developments within governmental, non-governmental, and scholarly arenas, all of which have been part of an ongoing global process of reimagining how archaeological work can, and should, intersect with community interests and needs.

Key Issues/Current Debates

A separate focus on communities as a *particular* arena for public archaeology began to emerge in the early 2000s, and these efforts slowly began to be referred to as "community archaeology" (Marshall 2002; Derry and Malloy 2003). Some archaeologists, also doing work with and for communities, did not frame their community-engaged work as "community archaeology" per se, but in a variety of other ways. One of the more recent frameworks would be "archaeological ethnography" (see Castaneda and Matthews 2008 and Mortensen and Hollowell 2009). Other frameworks include applied anthropology, heritage, activist or civically engaged archaeology, and participatory action research (see "Further Reading" for references). Finally, some of this work has been framed as simply "public archaeology" (Skeates et al. 2011) although some of this was also seen as specifically political in nature (McDavid and Babson 1997). Many of the same writers appear in books which were organized under all of these different approaches, and there is a great deal of overlap and conflation of indentifying terms.

The following are some features that have emerged in many community archaeology projects over the last decade:

- It acknowledges the community as a unit of identity that exists – whether or not "outsiders" (like archaeologists) indentify or recognize it.
- It also acknowledges that sometimes communities are constructed *by* archaeology projects – new alliances are forged, which, over time, can extend well past the boundaries of one archaeology project to address larger issues, such as social justice and housing equity.
- It recognizes that the idea of "community" is flexible and fluid and that each community person (and each archaeologist) is likely to claim many different community identities at the same time. That is, multivocality exists, and people tend to move between different communities and affiliations as their own needs and agendas dictate.
- It builds on community strengths and resources to gather, interpret, and publicly present different kinds of knowledge and to enhance archaeological knowledge. Therefore it often relies on interviews, maps, oral histories, ethnographic information, and photographic and video archives in order to integrate these resources into formal research designs.
- There is a strong focus on communication, collaboration, and equitable partnership. Ideally, all collaborators should be involved in, and empowered in, all phases of the research. Even when this ideal is not feasible, the goal is always foremost.
- It is sensitive to (and, importantly, informed about) any social inequalities that may exist in any given community context.
- It fosters co-learning and capacity building among all partners, including the development of employment and training opportunities whenever possible.

- It attempts to provide mutual benefit for all partners, whether that benefit be intellectual, political, or monetary (such as merchandising).
- It is focused more on the relevance of the research to *local* community issues than to larger academic research questions, although these goals are not mutually exclusive. Ideally all partners respect and recognize the right of other partners to achieve personal goals as well as group goals within the context of any given project.
- It distributes research results to all partners and involves all partners in their wider distribution and public presentation.
- It recognizes that community work involves a long-term commitment by all participants. There is commitment to sustainability even as individual players may change over time.

The above criteria draw on writing by Moser et al. (2002) and Mayan and Allen (2010), as well as the other case studies referenced here. Although this sort of listing can be a helpful jumping-off point when attempting to operationalize community archaeology (how does one *do* it?), it is important to recognize a very important aspect of all community-oriented work: it is *not* "one size fits all." Strategies, goals, and methods that work in one geographical, political, economic, social, or cultural context may not – probably will not –work for another. Therefore, community archaeology projects which *start* with in-depth research about the *individual* community – what one might call "contemporary context" or sometimes "ethnographic" research – are often the most successful.

This is true whether "success" is measured in archaeological or community terms – although it should also be noted that *evaluation* of community archaeology projects (and public archaeology projects in general, for that matter) is an under-explored but potentially important area of research. Thus far, most evaluation efforts have been aimed at developing "do's and don'ts" rather than examining the principles that underlie the development of any particular community or public project.

International Perspectives

These comments were written from the vantage point of practice in North America, although examples of community archaeology seen in this way have occurred all over the world. In the United Kingdom and Australia, however, the idea of "community archaeology" is slightly different and refers mostly to the practice of archaeology *by* communities. A good example of archaeology in this context would be Faulkner (2000). There is an active online listserv discussion group (http://www.britarch.ac.uk/caf/wikka.php?wakka=DiscussionList), as well as a long-standing journal, *British Archaeology*. Although the projects defined in this way are often (though not always) field-directed by a professional archaeologists, the overall direction and workforce is usually community- and/or amateur-driven. The main thrust is to involve local communities in archaeology and, as noted on the website of the Council for British Archaeology, to promote "the appreciation and care of the historic environment for the benefit of present and future generations" (http://www.britarch.ac.uk/). This echoes and supports the idea of "stewardship" mentioned above, but the work itself tends to be somewhat more "bottom-up" with respect to community involvement in various phases of archaeological research.

This idea is roughly equivalent to the idea of "avocational archaeology" in the United States, in which projects are conducted with large numbers of volunteers who have varying degrees of training. In many cases, avocational archaeologists are extremely skilled, especially with respect to field methods and material culture analysis (such as ceramics and glass). Avocational archaeology projects are very active across the United States, even when they are not necessarily referred to as community archaeology. Texas, for example, has the very active Texas Archeological Stewards Network (TASN, located at http://www.thc.state.tx.us/stewards/stwdefault.shtml) in which trained volunteer stewards find, record, and monitor archaeological sites; give talks to schools and preservation groups; assist professional archaeologists

on digs and surveys; and many other activities. Field direction is provided by trained professionals in all cases, even if the labor includes volunteers.

Future Directions

One positive feature of the most recent writing about community archaeology, likely to extend into the future, is that it tends to cross the usual disciplinary lines (arguably more so than earlier writing, which tended to be situated within the typical geographic and temporal discourses such as prehistoric archaeology, classical archaeology, and historical archaeology). In the past, a typical historical archaeologist/community archaeologist, for example, might not be conversant with work done by an Africanist, or an Egyptologist, or a prehistoric archaeologist, simply because they go to different conferences, read different journals, and so on. As this trend has evolved, particular methods and approaches common to community work in general have begun to emerge, as noted above.

Regardless which specific approaches are used in any particular project, many archaeologists are also now questioning earlier taken-for-granted definitions of the word "community" (e.g., Agbe-Davies 2010, and the contributors to Matthews et al. 2011). Whereas a somewhat traditional notion of community (referring to the descendants of a site and/or the locale around it) is still commonplace, not all communities fall into this sort of easy category, and community archaeology research and practice are starting account for this. A related idea has also emerged in the more recent work – the idea of "stakeholders," with stakeholders being loosely defined as any entity (person or group) which *sees itself* as having a stake in any particular site or project.

Seen in this way, stakeholders and communities are not necessarily defined by either professional archaeology or even supporters of it. For example, commercial developers could be said to have a stake in what they are allowed to build or not build on any given property. In some locales, developer "communities" have caused the destruction of many archaeological sites, even when neighborhood communities have emerged to resist this destruction – with varying success. In the same sense, antiquity dealers have a stake, as do "looters" (bearing in mind that this negative term sometimes includes descendants who regard archaeological remains as a legitimate cash crop which they have the moral right to exploit) (Velzen 1996; Hollowell 2006). In all of these self-defined and other-defined communities, context-specific tropes about power, property ownership, culture, and politics are at play. Therefore, the best community archaeology research (and practice) does not take any definition of community (or stakeholders or descendants) for granted. A critical, reflexive perspective is essential.

There is also a need to critically consider the desired results for community archaeology projects. Are they conducted so that archaeologists can better understand the communities they work with? Or are they meant mainly as a way to share archaeological research? Or are they a way for a community to better understand itself? In practice all of these sorts of understandings are developed, but not all are given priority in archaeological writing. Therefore one goal for future work would be to find better collaborative and open ways to write about the particular types of knowledge that emerge in community work.

Another goal would be to examine the reciprocal and long-term processes of both inclusion and exclusion. What does "inclusion" look like? Does it extend to offering communities the opportunity to review archaeological work? If someone from a community has a seat at the archaeological table, what are that person's responsibilities? By the same token, what are an archaeologist's responsibilities to a community which has, over years sometimes, acquired a stake in the work itself? Or in the archaeologist personally? Even though the last decade has seen a huge growth in community archaeology projects, few archaeologists have explored how this work plays out in the long run. Traditionally, archaeologists have tended to think of their work in terms of individual projects, which normally have a beginning, a middle, and an end. The work begins, community alliances and networks are built, and then what? What happens when a new project beckons?

Obviously the answers to this vary, but the point is that it is difficult for a community-engaged archaeologist to simply move on to the next project because both ethical and personal responsibilities need to be accounted for. These responsibilities are both to the communities involved and to the data itself. With regard to the data, once a project moves past the excavation/research stage, if the archaeologist remains connected to the community, his/her role usually shifts from "researcher" to one which is more concerned with public interpretation (museums, displays, etc.). How involved can or should the archaeologist continue to be? Can becoming less involved at that point allow more space for interpretations of data to change or be cast in ways that the archaeologist did not intend? When these public interpretations include mass media outlets, like television, non-archaeologists will be the ones who are reinterpreting, or reframing archaeological findings to suit other needs. Is this necessarily a bad thing? Some sites are, for good or ill, much more appealing than others to outside interests – whether those interests be Hollywood or a local public radio station. Can or should the archaeologist be concerned with how this plays out over time, for any particular project?

In terms of communities, things become complicated in part because *new* communities are often formed around the archaeological process. Friendships are formed and alliances are built, and often these alliances are aimed at solving community-wide concerns, not simply archaeological ones. This is especially true when archaeologists are working with communities which are disempowered for one reason or another – for example, when neighborhoods are fighting gentrification or when a community is endangered through a construction project of some sort. Even just considering "project-related" concerns, often there are fundraising and administrative duties which the archaeologist is used to expediting, which a community sometimes finds difficult to take on after the archaeologist leaves. Often funding cannot be obtained to keep the post-excavation work going – the outreach, the oral history interviews, the kids' programs, the museum displays, etc. During research phases of the work, often this work is done by the archaeologist who is trying to generate interest and get local input and publicity (and gather data). Local community groups usually have few resources to fund this sort of activity as paid work, and if/when the archaeologist leaves, it is all too easy for the work itself to falter.

It is true, of course, that these concerns are sometimes more important to archaeologists than to communities themselves – like everything else, each context and situation are different. A useful framework to consider these issues, and how they play out on the ground, comes from the "participatory action research" literature (Stoecker 1999). The idea is that archaeologists take on different roles, which vary according to the project, the individual archaeologist, and the community being engaged with. One such role is that of the "initiator." When acting as "initiators," the archaeologist comes up with a research or project idea and invites the community to participate – and keeps the process going, as described above. Another potential role would be the "consultant," in which the community commissions the research and the academic is accountable to it. In some scenarios – perhaps the "ideal" ones – the archaeologist is positioned as a "collaborator." Here the *community* would be driving the research, including partnering to formulate research questions, analyzing results, *and* keeping the process moving.

Chip Colwell-Chanthaphonh and T. J. Ferguson described these processes slightly differently in their discussion of a "collaborative continuum" (Colwell-Chanthaphonh and Ferguson 2008). The idea here is that all collaborative and community projects fall at one point or another on a continuum and a project's location on it can shift over time or as different players become involved. The questions that emerge in all of these scenarios could be:

- Do some public/community/collaborative efforts simply have a life cycle?
- To what extent should "capacity building" be a part of what archaeologists *do* – for some sorts of projects? If so, what would this look like – training, workshops, or something else?

- How do (or should) archaeologists devise ethical exit strategies from projects which have reached either a natural or unnatural end, or in which archaeological input work is no longer needed, or even just when the archaeologist reaches a point of wanting (or needing) to become less engaged?
- How do issues about "sustainability" play into the decisions that archaeologists and local communities make? How can projects sustain themselves in the face of contemporary financial challenges and the evolving interests and skillsets of individual professional and local collaborators?

Inclusive community-engaged projects are still not embraced by all archaeologists. Some still prefer to focus on purely academic agendas, and others resist mutually empowered scenarios which allow nonscientific views of the past equal standing. Even when an archaeologist is personally motivated to include community input (or, even, review) as part of her/his practice, there are often constraints which work against this – client restrictions, for example, are commonplace in contract, or commercial, archaeology.

It is also important to remember that archaeologists themselves are embedded in professional communities as well as academic, national, political, epistemological, and ontological communities of practice. The question in these contexts is not *whether* to engage; rather, it is to look at how engagement itself helps to define what archaeology is and what it accomplishes. Community archaeology, seen in this way, is not work that archaeologists choose to do, but is inherent to how archaeology is practiced.

Archaeologists are only beginning to competently understand and ethically engage with collaborating communities and to examine whether this engagement serves interests beyond those of archaeologists and related heritage professions. They are only starting to understand the roles that community members play in collaborative archaeology projects – that is, who participates and who does not and who is excluded and who is not? How do these performed roles reflect (or not) the roles that collaborators play in their communities *outside* of their relationships with archaeologists? What is the potential for community archaeology to be actively dialogic? Can a deeper and more developed understanding of communities be deployed in the archaeological research performed so that archaeology is not only "in" and "with" communities but "about" them as well? Can archaeological community engagement reveal and address "community-building" issues otherwise obscured by acts of inclusion and exclusion? How, or do, the communities formed through archaeology projects create new knowledge that is relevant to archaeologists and communities alike? Do they add to an informed understanding of the archaeological past?

On a different scale, archaeologists are also starting to contextualize community archaeology within the influential national and global trends already in play. What external and internal forces and goals motivate community members to take an interest in archaeology? Do imagined and actual intersections between archaeology and communities speak to the relationships between community members and other outside interests such as nonprofits/NGOs, interests in education and business, or deeper social and cultural interests of national and global capitalism?

Community archaeology has come of age in the last decade as one important form of public archaeology. At its most basic, community archaeology is the practice of working in and with communities during the archaeological process. Although, in its original forms, this was an educational endeavor, as the subfield developed, communities for archaeology have become far more than passive recipients of archaeological knowledge and expertise. Instead, community archaeology projects are now at the vanguard of creating a multivocal, inclusive knowledge-building process in which archaeology as it is traditionally practiced is just one of many routes to knowing the past.

Community Economic Development and Archaeology

Peter G. Gould[1] and Paul Burtenshaw[2]
[1]Penn Cultural Heritage Center, University of Pennsylvania Museum of Archaeology and Anthropology, Philadelphia, PA, USA
[2]Sustainable Preservation Initiative, Los Angeles, CA, USA

Introduction

The intentional use of archaeology as a tool to promote community economic development has increased significantly over the past few decades. Archaeologists utilize their field activities to benefit communities in which they work, and development practitioners have recognized that archaeological research and heritage sites can provide a foundation for economic growth based on tourism. Archaeological engagement with development has not been without controversy within the field, both regarding the ethics of the engagement and the actual benefits for local communities that result from site museums, tourism initiatives, and other local development projects. Furthermore, experience in the field is generating important lessons about the resources and practices required if archaeology is to contribute successfully to local economic development. Perhaps the most salient of those lessons is that archaeologists' academic training leaves them relatively ill-equipped when it comes to promoting development. Greater exposure to development practice, and focused exposure to the challenges of development projects, will be required if archaeologists are to continue to engage in community economic development.

Definition

Archaeology, in this context, encompasses all aspects of practice in the field, from excavations and field schools, to museum development, to the preservation and public use of archaeological sites. Every aspect of archaeological and heritage management activity has economic consequences, and the benefits as well as the costs of those activities may be felt at the level of local communities.

Community is a term freighted with contention and ambiguity within and without archaeology (Smith and Waterton 2009, Chapter 1). In the discourse around community economic development and archaeology, however, "community" most often refers to a "local" community that is defined by geographic proximity to a tangible cultural heritage. The individuals in that community may live together harmoniously, or not; they may have parallel economic interests, or not; and their identification with the heritage itself may range from profound to indifference. The challenge for any community development project is to bridge these differences, negotiate the interface between the community and outside actors, and identify the archaeological activities and economic programs that the community itself can benefit from most directly.

The "local" community tends to be where archaeological excavations and heritage site management interact with individuals, whether as sources of labor, accommodation and provisions, or, in post-processual settings, as sources of knowledge and expertise. This is where archaeologists develop relationships with community members. Equally, those who live in closest proximity to heritage sites typically will have the most direct, sometimes contentious, relationships with sites that occupy a part of their local environment and intrude into everyday life. Those in closest proximity to sites are most likely to act in detrimental ways (e.g., grazing, reuse of materials, or looting) but also can be key allies in heritage protection because they may benefit most from site development and are in the best position to protect it from outside forces. The scale of a community geographically close to sites can vary widely, particularly between dense urban, and more dispersed rural, populations. As the size of the "local" community scales up, the complexities of working with diverse groups of individuals and defining effective strategies for community economic development become increasingly complex.

Economic development is a notion rooted in enlightenment concepts of progress but identified in recent decades with the unfolding economic and political structures that followed on the breakup of European colonial empires in the period after World War II. Development programs have funded investments in infrastructure, agricultural productivity improvements, industrial expansion, and the growth of service industries, both in former colonies and other countries whose standard of living lagged European and North American counterparts. Development, which is measured primarily through increments in gross domestic product (GDP) per national resident, has traditionally been the responsibility of national government agencies and large international governmental organizations (IGOs) such as the World Bank and its affiliates. This so-called "top-down" development process has been largely expert-driven and controlled from national and international centers. As will be noted below, however, this discourse is changing.

Thus, archaeologists' engagement in local economic development projects reflects a larger trend among governments, IGOs, and nonprofits to pursue programs that have tangible, positive impact on local communities. These efforts have led to experimentation in the organization and management of community projects; in programs to increase the skills, financial capacity, and market access of community groups; and in research to understand the metrics for success of community-level projects. Archaeologists have played a small role in that work.

Historical Background

Archaeology has come increasingly to be seen as a resource to promote economic development at the community level. This perspective, which has emerged gradually since the 1970s, is the result of the intersection of vectors of change in three separate fields: changing views within archaeology on the goals of the discipline and the responsibilities of archaeologists; transformation of the narrative in the development field toward a sustainable development agenda; and the emergence of a global tourism industry, built largely on cultural heritage resources, that has captured the attention of national governments and international development organizations.

Neither economic development nor community engagement was central to archaeological practice for most of its history. Even though the study and preservation of cultural heritage has proceeded with implicit, and sometimes explicit, understanding that the work was done for public benefit, archaeology through the end of the colonial era was largely practiced for academic inquiry and, to a degree, nation-building on colonial terms. With the breakup of European colonial empires in the aftermath of World War II, the challenge of economic advancement for former colonies became a focus of international organizations such as the United Nations and a preoccupation of nations contending for global leadership, particularly the United States and the former Soviet Union. In the same period and to some degree as a response to decolonization,

archaeologists adopted reflexive perspectives on their discipline that shifted the focus from the heritage itself to the peoples and communities whose heritage was under study.

In the 1970s and 1980s, the rise of public archaeology and the increased recognition of indigenous peoples' rights to their own past constituted a purposeful attempt to use archaeology for the public good and especially for disempowered communities. The process began with the self-interested perspective that increased public involvement in archaeological activities would augment the archaeological work force and build a constituency for political action to support archaeological research (McGimsey 1972).

Perspectives have changed considerably since then. Today, outreach to local communities to involve them in the process, share findings, and provide educational opportunities is essentially a best practice in the field. Archaeology's postcolonial ethical discourse extended those obligations to acknowledge both the agency of local, especially indigenous, communities and the potential that "multivocal" perceptions of archaeological findings could contribute meaningfully to interpreting the archaeological record. More pragmatic concerns also gained salience. The emergence of a robust antiquities market led to increasing concern to prevent looting, and the pressures of development focused the discipline on strategies to prevent local acts of heritage destruction. Some archaeologists have concluded that their ability to carry out their own projects has been enhanced through good community relations that include providing benefits to the community, and others have adopted ethical stances that communities should have a leading role, if not the leading role, in determining how their local heritage will be explored and exposed to the broader public. While every community will have a unique relationship with local cultural heritage, archaeologists, especially those working in developing countries, have found that the benefits most often relevant to local community members are economic.

National governments have focused on cultural heritage for other reasons. Nation-building by newly independent countries often has centered on cultural heritage and historical narratives informed by archaeology. An important, alternative motivation for government support for heritage, however, is the important contribution to national economies arising from the dramatic increase in global tourism. This has affected economically advanced countries of the global north and has become especially critical to countries emerging from colonial rule in the southern hemisphere. From virtually nil in the 1950s, international tourism arrivals have burgeoned in the current decade to more than one billion travelers per year globally. Advances in air travel, growing incomes and access to leisure time, and promotional efforts by tourism companies have combined to make tourism a major contributor to economic activity in places like the United Kingdom, Italy, or Greece and made tourism a vital economic engine in emerging countries in Latin America, Asia, and parts of Africa. This tourism is driven largely by travelers' desire to visit historic sites and iconic landscapes and to experience for themselves the cultural heritage of other people. If archaeologists have asked themselves about the societal relevance of archaeology, it is now clear that economic development, driven by archaeological research and heritage management, is among the essential answers.

Finally, the narrative about economic development has transformed in recent years. For decades after World War II, neoliberal policies of free markets, fiscal and monetary austerity, and openness to international trade dominated strategies among international development agencies and national governments. In recent years, disappointment with the effectiveness of neoliberal policies and concern that free-market development has not benefitted the broad public in many countries have led to a shift in perspective, especially amid a growing realization that increases in GDP involve collateral damage to the environment and to important cultural resources and community coherence. Neoliberal market rhetoric has given way to a search for policies more likely to deliver widespread and equitable development to emerging economies. The metrics for successful development have expanded beyond strictly economic measures to incorporate social, cultural,

and environmental factors key to long-term improvements in the quality of life. Beginning with the Brundtland Report of 1987 (WCED 1987), the idea that "sustainable" economic development requires the preservation of resources (including the environment and heritage) for future generations has become embedded in the international development discourse through a sequence of global summits. These concerns for the impact of development projects have resonated at the local level, driving recognition that development programs need deeper roots in local communities if they are to be successful. Even the World Bank has pursued policies seeking to promote "local community-driven development" (Binswanger-Mkhize et al. 2010).

The role of cultural heritage in economic development has only grown as the development narrative has transformed. This is particularly visible in international charters and the policies of international organizations and nongovernmental organizations. Sustainability has become a theme in the work of the United Nations Educational, Scientific and Cultural Organization (UNESCO), whose own conclaves have generated a series of international agreements on the protection of heritage, the Hague Convention of 1954; trade in cultural property, the Paris Convention of 1970; the concept and protection of World Heritage, the World Heritage Convention of 1972; and many others. Increasingly, these agreements incorporate explicit references to community engagement and economic development as part of sustainable cultural heritage practice. The Council of Europe's Faro Convention of 2005 explicitly places people and human values at the center of the concept of cultural heritage and acknowledges the potential contribution of cultural heritage to sustainable development. The role of heritage in urban development achieved global recognition with the adoption of the UN's Agenda 21 for Culture in 2004, and the International Council on Monuments and Sites devoted its 17th general assembly in 2011 to the topic, "Heritage, a driver of development." In the international legal and ethical discourse on sustainable development, heritage's central role is well established, as is the obligation of heritage managers to place local community considerations at the center of their work.

Perhaps unsurprisingly, given this history, the rhetoric of archaeology as source of economic benefit also has built expectations within communities. Community members increasingly expect those conducting projects in what communities consider their local domain to deliver both interaction, in the form of educational and communications efforts, and economic benefit. National governments increasingly are making excavation permits contingent on local participation in archaeological projects, by both indigenous archaeologists and community members. Artifacts once distributed internationally under a system of "partage" now generally remain where they were discovered to endow local and national archaeological museums. Reflecting the shifting ethos within archaeology, both individual archaeologists and international nonprofits have attempted to encourage and underwrite community-based cultural heritage projects intended to bolster local economies.

The confluence of these three vectors of change – in archaeology, in the economic value of tourism, and in the international development narrative – has produced a contemporary situation in which it has been argued that "it is development, rather than conservation that shapes the diverse work of archaeological practice in the world" (Lafrenz Samuels 2016, 355). In turn, this has produced a growing, frequently critical literature and numerous attempts by archaeologists to promote community economic development. Some projects have generated meaningful success, but disappointments abound. There exists a growing recognition that archaeological engagement with community economic development is in its infancy, with central issues and debates on ethics and practice still to be resolved.

Key Issues/Current Debates

It is important to note at this juncture that the literature examining the impacts achieved by archaeologists through local community development projects is sparse and characterized by a lack of explicitly stated goals and data with which to track the achievement of those goals. Many archaeologists are familiar with examples

of attempts by archaeologists to pursue community projects such as the erection of local museums and visitor centers, local craft projects, or local skills training. Some success stories have been told, but many archaeologists also are familiar with projects that failed to become sustainable. That is, they failed to attract funds (either from visitors or elsewhere) to continue to provide the educational or economic missions they were established to carry out. Widespread, systematic, and thorough reporting and evaluation of such projects, however, remains an unfulfilled agenda within archaeology.

Archaeology and cultural heritage management projects affect local economies both through direct interventions and through the beneficial consequences of tourism. Direct impact on local communities comes from field excavations, heritage preservation and conservation projects, and the spending impact of archaeological field schools. Local people will be employed for unskilled tasks and, in many cases, become skilled excavators or conservators in their own rights. Project participants require food, accommodations, and sundry items. Although projects generally are small in scale, the local consequences can be meaningful, especially if projects continue over a number of years. Because of the volume of visitors to recognized heritage sites, however, the economic impact of heritage tourism is the most significant economic force at the national and the local level. Local communities gain income from providing various services to visitors including accommodation, food, guiding, and souvenir production and sales. Local merchants benefit from the patronage of community members whose incomes are rising because they are directly engaged with tourism. Along with these benefits, however, have arisen important concerns about both policy and practice. Reflecting findings from examination of projects by the World Bank and UNESCO and the experience of nongovernmental organizations, three general categories of issues and concerns emerge clearly from experience in the field: the problem of community empowerment; the extent and value of the actual impact; and the challenge of endowing local communities with sufficient skills and resources to benefit meaningfully from archaelogy-related activities.

Community Empowerment

Local communities ordinarily have limited control over archaeological activities within their borders, often with traumatic consequences for community members and the heritage itself (Comer 2012; Meskell 2012). Project approvals typically are issued and supervised by government officials. Managers of the site often are specialists with formal qualifications beyond the reach of members of local communities. Local communities are typically not involved with the conversion of their site into a tourist destination and do not benefit from ticket sales or on-site commercial opportunities, which often are controlled by state authorities. Even site guides may require formal training and licensing from which local residents are excluded. Locals may find themselves excluded from the site itself if their presence does not conform to the image tourism officials seek to project. Even if a destination is developed by local communities, they may not have the resources for large-scale promotion and infrastructure needed to attract tourists and so lose any agency over the course of development of their own community heritage.

The vulnerabilities of weakly empowered communities have been documented in numerous regions of the world (Aas et al. 2005; Hampton 2005; Zorn and Farthing 2007; Adams 2010; Meskell 2012). Although the principles of good practice in public and community archaeology emphasize active engagement with stakeholders in communities, every tourism venue features a diverse range of stakeholders, many from outside the community and some, such as UNESCO, outside the country. Outside stakeholders typically have greater access to tourism industry expertise, financial capital, and political power. Meanwhile, local communities themselves may be riven with factional differences based on family, religion, or other factors. It is insufficient for local communities simply to "sign off" on economic development projects associated with their local cultural heritage. Without clear legal empowerment and strong local governance of the tourism activities, sustaining community heritage tourism has proven to be a significant challenge. Even in cases where community governance and national law have converged to empower local projects, such

as in the Val di Cornia in Italy, shifting national political and economic fortunes and local political conflicts can undermine even established and successful community-based heritage tourism projects (Gould 2018, Chapter 7). Although limited efforts have been made to identify the features of community governance that may give rise to sustainable outcomes, generalizable approaches to community empowerment remain to be articulated and enshrined in laws and in archaeological practice.

Actual Impact

Field schools and conservation projects offer another route to economic impacts. The jobs created in such projects can have important local impacts (Boytner 2014; Pyburn 2017). If projects continue over multiple seasons, they can provide predictable income to the local community. However, these are usually seasonal positions and completely dependent on outside funding, which can end leaving even trained conservators and excavators without means of employment (Roca 2017). While there are many examples of local community members becoming qualified archaeologists or conservators under the mentorship of long-term local projects, in many developing countries, management and skilled positions within excavations are predominately held by foreigners. Field school workers, generally students from the United States or Europe, are performing roles locals can easily be trained to carry out. In some settings, the need to distribute employment widely and fairly within a community prevents pay based on experience and minimizes each individual's income. A notable counterexample is the Temple of the Winged Lions Project in Petra, Jordan (Tuttle 2013): the original research project ensured that local community members were trained in conservation and research skills. Subsequently, supported in part by international development funds, the local community is now attempting to run an archaeological conservation services and training company (see selatrainingjo.com).

Similarly, efforts to generate income at the community level through projects that service the tourism industry directly have been successful but limited. There are real practical barriers to communities benefiting economically from visitors. Depending on distances and available amenities, tourists may not spend significant time or money in the community on accommodation or refreshments, with the actual benefits of tourism flowing to regional centers or beyond. Where local spending does occur, the impacts may attract nonlocals with more capital and experience in the industry who are better able to take advantage of opportunities. Local production of souvenirs has proven to be a modest contributor in many communities, but communities aspiring to sell products offsite require the capacity to locate markets and establish distribution channels to serve them effectively. In general, the barriers to community tourism initiatives have not been overcome through the actions of archaeologists. Although data is often limited, what does exist shows that the rhetoric of projects is not matched by the reality (Hampton 2005; Adams 2010; Comer 2012). However, the example of Agua Blanca in Ecuador (Hudson et al. 2016) demonstrates that real long-term benefits are possible with favorable market conditions and long-term sustained engagement.

Skills and Resources

Experience around the world with projects seeking to benefit local communities through their archaeological heritage has taught that no success is possible without external assistance. Typically, in emerging countries, local community members lack knowledge of archaeological conservation and the requirements of the tourism industry. They lack access to political patronage necessary in many countries for projects to proceed and typically lack access to requisite financial resources. Not all economic development projects aim to establish a self-sustainable business, and short-term or seasonal employment may provide benefit for crucial periods to community members. Projects with longer-term ambitions, however, need sound business plans and access to skilled external supporters.

In practice, archaeologists rarely collect the information they need to ensure that the economic activity they initiate can be sustained (see case

studies in Burtenshaw and Gould 2015; Gould and Anne Pyburn 2017). This is particularly true with regard to gathering information on the market local businesses are designed to serve. Visitor information, albeit often flawed, must be collected. Expectations for the level of new tourism must be tempered in reality. Product-based businesses often focus on production of traditional goods rather than working to understand which products prospective consumers want to purchase. Also required is a comprehensive understanding of suppliers and costs of production in order to ensure that the business can be profitable and provide employment at fair income levels for project participants.

The failed site museums and community crafts projects that litter the archaeological landscape reflect the need for communities, with assistance, to conduct thorough business planning and to couple those plans to effective and appropriate skills training and access to financial capital in the form of grants or highly concessionary loans.

If projects are to be self-sustaining over the long run, community leaders will need training in general business skills to manage financial aspects of the business and to adapt it to changing circumstances. With a workable business plan in hand, communities will need help to acquire the specific occupational skills needed to run a project without ongoing outside help. They will need substantive archaeological knowledge to serve as guides, and marketing and technical guidance to produce marketable products. The Sustainable Preservation Initiative (SPI) (sustainablepreservation.org) attempts to create sustainable community businesses associated with local cultural heritage in several countries. A key part of its strategy is that local project managers are guided through the diagnostics of assessing the market and understanding what businesses are viable and sustainable. Equally, SPI tries to ensure that local community members receive a "mini business school" which teaches them the basics of business governance, planning, accountancy, marketing, and product development so that they can manage their own businesses over the long term.

Moreover, not all members of a community will wish or be able to participate in a development project. Participants will need to manage potential frictions from within the community and to insulate the project from outside governmental or commercial interlopers. Even with a viable business plan in hand, community projects need effective organizational governance that is led by motivated community members, not outsiders (Gould 2018). Local community members need to be involved in the creation of projects from the beginning, must concur in final plans in order to ensure projects are locally relevant and supported, and must provide leadership to the project once it is launched. These conditions imply limits on the role of archaeologists and other outside advisers, who can provide assistance, advice, and insight but must not displace community members in leadership roles.

International Perspectives

Interest among archaeologists in participating in community economic development projects varies widely around the world, reflecting varied local political and economic contexts on one hand and local disciplinary imperatives on the other. From a geographic perspective, archaeologists working in countries with more modernized economies are more likely to operate within the context of government and private-sector economic development agencies with the skills and resources to promote industrial scale tourism and urban renovation projects. Archaeologists in these contexts are least likely to be found leading development efforts. Public archaeology programs are more commonly the vehicle through which archaeologists engage with communities in such settings, which include the United States, the United Kingdom, and parts of Europe. Where economic conditions are less advanced, archaeologists may more frequently be encountered supporting development projects rooted in archaeological sites and heritage. Countries with emerging economies tend to be the focus of archaeological NGOs that sponsor development projects and of projects sponsored by individual

archaeologists in conjunction with their own scholarly endeavors.

Interest in community development through archaeological projects also varies in response to differences in the scholarly, social, and political priorities of the discipline globally. Again, regions of the world that are less developed have been the object of more efforts to promote development led by socially conscious indigenous and foreign archaeologists. Heritage professionals have been deeply involved in the development of ecomuseums, primarily in Europe and other regions with advanced economies, but development efforts associated with archaeological heritage in those countries have often been led by government agencies. Archaeologists are less engaged in development in European segments of the Mediterranean region, perhaps because archaeologists trained in classical disciplines have been less exposed to the practical and ethical issues in developing countries that are routinely encountered by archaeologists trained in anthropology, who work more often in less advanced settings. However, concern for community development has been increasingly evidenced in practice and in ethical codes across the archaeological disciplines and throughout the world.

Future Directions

Archaeologists' engagement in community economic development is, to a degree, at a crossroads. Initial enthusiasm about the prospects for cultural heritage to enhance local community economies, although clearly successful in many parts of the global north, especially in Europe and the United States, has been tempered by experience elsewhere. Ill-thought-through projects, lacking in market understanding, have been pursued in communities that lacked skills and organization and faced daunting economic, political, and social challenges. Not surprisingly, results have been disappointing. Successes, where they have occurred, have been projects that are led by local community members who took the lead to build their own heritage-based economies and benefitted from advice, training, and support delivered in ways that reinforced, rather than undermined, the leading position of the community itself.

This reality has led some to question whether archaeologists belong in the economic development business (Pyburn 2017). The factors that have propelled archaeological engagement with community development – disciplinary ethics in archaeology and heritage management and the growing focus of the development industry on sustainable bottom-up projects – show no signs of abating, however. Thus, calls to make heritage and archaeological sites economically valuable to their host communities are likely to continue. This means, at a minimum, that the sobering experience to date needs to prompt reconsideration of the strategies of individual archaeologists and nongovernmental organizations rooted in the field. Practice needs to change substantially to focus on business training, market analysis, supply chain management, community governance, and comprehensive, light-touch external assistance.

For changes in practice to be successful, however, more systematic examination of current and past projects is required. Objectives need to be defined, and data on their achievement need to be gathered. Both short-term and long-term studies of successful, and unsuccessful, projects are needed to begin to define best practices in a manner that can be transmitted to practitioners in the field. Thus, an ambitious research agenda into what works, and why, should be at the heart of future archaeological interventions in pursuit of community economic development.

Community Engagement in Archaeology

Anna S. Agbe-Davies
Department of Anthropology, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA

Introduction

For generations, archaeology has been conducted for, and shared among, a small group of scholars, but now many archaeologists consider "community engagement" to be an important part of their work. Archaeologists may make special efforts to share their interpretations in ways that are more accessible to a wide audience than are scholarly publications or even traditional museum displays and documentary films. Archaeologists may wish to see their research benefit modern groups with ties to the site through, for example, increased heritage tourism to their area or the enhancement of their status by drawing attention to the group's past. Archaeologists may believe that they have an ethical or political obligation to ensure that their research is beneficial to these groups. Archaeologists may even find that encouraging members of these groups to participate in their research increases their understanding of a site or improves their access to important data. Although all of the above are important, community engagement in archaeology extends far beyond these measures.

Community engagement means that archaeologists think about nonprofessionals as potentially active participants in, not simply passive audiences for, their research. It means that community members can influence the goals and outcomes of a project. It means that as a result of their close collaboration, archaeologists might learn things that change the way they approach a particular site or, more significantly, the methods and theories that they use to understand the archaeological record and interpret past human actions. These ideas are not uncontroversial. Many archaeologists are unconvinced that we can continue to consider knowledge production to be "science" once its political or ideological underpinnings are revealed. Such questions have been raised with respect to the "public" or "applied" scholarship produced in one of archaeology's sister disciplines: anthropology (but see Mullins 2011).

This paradigm shift has occurred in multiple disciplines. In archaeology, specifically, post-processual frameworks have developed research themes that inspire community-oriented work and also fostered the self-reflexivity that must underpin serious community engagement. But changes in media, communication, and travel also create structures which shape this relatively new way of approaching archaeological practice, as do contemporary heritage law and the global political economy. Thus, it seems that community engagement will be a feature of archaeological practice for some time to come.

Definition

Although many archaeologists initially became interested in community engagement through projects that connected them with the descendants of the people who created the sites they studied, researchers have come to realize that there are many types of communities for whom archaeology matters, who ought to be engaged. Certainly descendant communities have a special relationship to the sites and landscapes occupied by their ancestors, and their assertion of an authority on par with, or surpassing that of, archaeologists is increasingly supported by national and international law, as described below. However, other collectivities are considered by archaeologists to be legitimate stakeholders in the archaeological process. For example, people who live in the vicinity of archaeological sites form another kind of significant community – one that hews more closely to the traditional meanings of "community archaeology": the archaeological study of a past community, often defined by the proximity of its members or the scale of the group (larger than a household, smaller than a polity) (Canuto and Yaeger 2000).

The aim of community engagement in archaeology is to go beyond simply sharing the results of one's research with an audience with some claim to a site or social group in the past. Rather, archaeologists seek to produce scholarship that benefits that group, conceiving of them not as an "audience" but as a real constituency, one that has a very real stake in the outcome in an archaeological project. Furthermore, the aim of the archaeologist is to share power and responsibility with that group in the very act of research (see, e.g., Blakey 2010).

A good question to consider, then, is where does "public archaeology" end and "community engagement" begin? One useful distinction is the idea that public archaeology is any archaeological interaction with a public (i.e., non-archaeologists) and any scholarship analyzing these efforts. "Community archaeology" is public archaeology that creates the opportunity for all involved – community members and archaeologists – to reflect upon the ideas and interests that they share. It is furthermore less likely to be oriented toward scholarly interests than other forms of archaeological practice (McDavid 2009: 166). Some commentators emphasize the importance of community control over the archaeological project and in fact stress community engagement's transformative effect on scholarly research (see, e.g., Marshall 2002a; or Green et al. 2003). Indeed, archaeologists are growing increasingly self-reflexive in their discussions about what it means to do archaeology in the real world.

So here, "community engagement" should be taken to mean archaeology that responds to imperatives established by collectivities whose stake in the archaeological record is not professional but

rather stems from some other connection. Perhaps the site was occupied by their ancestors, or they live in the site's vicinity, or they identify with the site's inhabitants because of some shared status or identity. Whatever the reason, these people have a social connection with people in the past, people who left material traces that are amenable to archaeological study. As a result, these present-day people are connected with one another. When the connection extends to encompass the archaeological project as well, when the ideas of these community members have a meaningful effect on the research, and when their values and ideas are considered alongside those of the discipline, then we are speaking of community engagement in archaeology.

Historical Background

Milestones in the development of archaeologies of community engagement may be marked by the development of influential research programs. Other important watersheds include publications which are either reports describing these programs or synthetic and analytical treatments of the challenges and rewards of engaged scholarship.

Two early examples of community engagement in archaeology come from the Chesapeake region of the USA, an area with a long tradition of historical archaeology. The first, Alexandria Archaeology http://alexandriava.gov/historic/archaeology/default.aspx?id=39146, grew out of a community initiative to protect archaeological sites threatened by development. In 1975, the city established the Alexandria Archaeology Commission, hiring city archaeologist Pamela Cressey 2 years later. The program's aims include excavating sites, curating and interpreting finds, and especially providing opportunities for volunteer participation in preservation activities. By way of contrast, the second example, Archaeology in Annapolis, has tended to emphasize visitor education, rather than public participation, as central to their strategy for community engagement. Since 1981, tourists have been able to visit ongoing archaeological excavations and discuss life in the city from the eighteenth century to the present, using strategies and themes grounded in the project's Marxist approach to archaeology (see Potter 1994).

Elsewhere in the USA, work began at Little Rapids in the early 1980s as a traditional research project. But several years into the study, principal investigator Janet Spector's strategy shifted. Feminist concerns about bias and exclusion in scientific practice led her to critically reflect on what it would mean to

> include Indian people in the production of archaeological knowledge about their histories and cultures. How will this affect the ways we set our research agendas, organize field projects, treat archaeological materials? How would their inclusion shape the ways we generate, express and present our understandings of the past or the audiences we write for?. (Spector 1991: 389)

Similar concerns about the exclusion of indigenous people from the archaeological study of their ancestors – in addition to development pressures – led the Navajo Nation to establish the Navajo Nation Archaeology Department, wherein the archaeological and ethnographic staff must adhere not only to US laws but also to the laws and policies established by the Navajo Nation. While this mandate upholds the authority of Navajo people over the archaeological sites within their reservation, it does not mean that all of the people performing day-to-day archaeology are necessarily tribal members (Thompson 2009). The authority of the Navajo Nation to compel engagement and control archaeologists' access to materials is buttressed by federal legislation such as the Native American Graves Protection and Repatriation Act (NAGPRA). At the African Burial Ground http://www.africanburialground.gov/ABG_Main.htm in Manhattan, on the other hand, existing laws only mandated mitigation of damage to the archaeological resources, not engagement with any communities. The well-publicized struggle by New Yorkers and concerned African Americans to participate in decisions about the study and disposition of the burials has marked a major watershed in how US federal agencies and archaeologists work with descendant communities (see, e.g., La Roche and Blakey 1997).

At the same time that marginalized communities in the USA were becoming increasingly assertive of their right to the materials that archaeologists study, archaeologists working in economically and politically marginalized nations were teaming up with local communities in efforts that some labeled "applied archaeology" (Erickson 1998) and others, "action archaeology." The latter term is used by Mayanist Jeremy A. Sabloff to indicate "*involvement or engagement with the problems facing the modern world through archaeology.* In other words, by 'action archaeology,' I mean archaeologists working *for* living communities, not just *in* or near them" (Sabloff 2008: 17, emphasis in the original). Over the years, examples have included identifying ancient land-use techniques that promote higher crop yields than prevailing agricultural practices (Erickson 1998), creatively engaging host communities in site protection, promoting development http://www.savethemoche.org/ or educational http://www.machiproject.org/en/index.php projects in host communities, and incorporating local perspectives into research agendas (see, e.g., Atalay 2007).

The Community Archaeology Project at Quseir has had an extraordinary influence on how archaeologists approach community engagement. Most significantly, the scholars responsible for that project put forth a general methodology for engaged archaeology rather than a set of instructions or a how-to program (Moser et al. 2002).

The archaeological programs described above, and many others, are represented in, and paralleled by, a series of key publications. Notable contributions include collections of essays about engagement between archaeologists and indigenous communities and between archaeologists and members of the African diaspora. The issue of *World Archaeology* edited by Yvonne Marshall continues to have a major impact, not least because of its broad global scope. A recent collection compiled by Barbara J. Little and Paul A. Shackel emphasizes the role of archaeology in enhancing civil society, specifically (see McDavid and Babson 1997; Swidler et al. 1997; Marshall 2002b; Shackel and Chambers 2004; Little and Shackel 2007; Colwell-Chanthaphonh and Ferguson 2008; Bruchac et al. 2010).

Key Issues/Current Debates

Ever since archaeologists have discussed explicitly what it means to engage with communities, there have been disagreements about whether and to what end this engagement ought to take place. Parker Potter took early practitioners of "plantation archaeology" (now treated as a subset of African American or African diaspora archaeology) to task for failing to come to terms with the needs and desires of a broad-based descendant community of African Americans and for, in some cases, producing scholarship inimical to those same needs and desires. Responses to this critique included the retort that archaeologists should question their relevance not only to descendant audiences but also to scholars in other subfields who found archaeological studies of plantations to be arcane and irrelevant. Another dissenter rejected the idea that practitioners open the research process up to non-archaeologists or "that valid research questions and interpretations can be developed out of the contemporary agendas of groups on either side of the power line" (see Potter 1991; Farnsworth 1993; McKee 1994: 5).

While it might seem that a decision on the part of archaeologists to further engage with communities would be beneficial, or at worst, harmless, concerns have been raised, many of them centering on the idea of *which* communities merit engagement and on what terms. In a recent essay concerning the usefulness of archaeology, Shannon Lee Dawdy considered whether public archaeology and its related forms might be a stalking horse for a range of nationalist agendas. She sees this as a special danger in settings without a long history of (and therefore wariness about) nationalist archaeologies, or in settings in which archaeology is meant to be of use to a subaltern community. Though engagement is often meant to benefit the marginalized, archaeology can also serve powerful statist and extra-governmental interests, and Dawdy's essay asks

that archaeologists critically reflect upon the distinction. Archaeologists from a variety of employment sectors and across the globe responded to this analysis by refining the distinction between "public" archaeology and "community" archaeology (as described in "Definition," above) and providing concrete examples in which archaeological practice benefited constituencies besides archaeologists or the structures (institutional, economic, and political) that underpin archaeology's existence (see Dawdy 2009).

Many of the practical advances archaeologists have made in engaging with communities have been in the exploitation of new media environments. Just as newspapers and novels, the new media of the early modern period, were instrumental in creating alternatives to a purely local "community," the new media of the new millennium have allowed archaeologists to connect with others in fruitful ways. Archaeologists easily grasped the potential for the Internet to multiply the number of individuals who could "experience" a site or to communicate interpretations to colleagues and other interested parties. However, some have realized the ways in which the Internet can be used to facilitate collaboration and dialogues – to support the process of engagement. An early pioneer in this effort is Carol McDavid, whose work at the Levi Jordan Plantation was both a product of and an engine driving the project website http://www.webarchaeology.com. Such endeavors have only grown with the introduction of Web 2.0 technologies and the ascendance of electronic social media.

Archaeological associations and university departments have begun to explore how best to incorporate community engagement into archaeological education generally and especially how to expose future archaeologists to ideas about community engagement. An educational movement that has gained considerable following in universities in the USA is "service learning" in which students' intellectual and civic education is enhanced by opportunities to apply the principles of a particular discipline. As Michael Nassaney observes, this form of pedagogical practice is ideally suited to a hands-on, experiential endeavor such as archaeology (Nassaney 2009).

In the Society for American Archaeology's volume *Teaching Archaeology in the Twenty-first Century*, community engagement is presented as one of several areas that need additional attention, as educators consider the skills needed by emerging practitioners. The toolkit for archaeologists who effectively engage communities includes respect for different points of view, intensive coursework in ethics, an appreciation for the heterogeneity of communities, and a strong sense of professionalism. These matters are so important because, as the authors of one contribution conclude, "it is hard to deny the proposition that the social context in which archaeological research unfolds influences directly both the quality and efficiency of fieldwork and the validity of the knowledge that it generates" (Watkins et al. 2000: 80–1). The transformative effect of community engagement on archaeological knowledge is explored further below, under "Future Directions."

International Perspectives

Several observers have noted that the most prolific (English-language) writing about community engagement in archaeology comes from former settler societies – modern states with origins in colonialism and settlement by a foreign power, with continuing power imbalances between descendants of settlers and descendants of the indigenous inhabitants. It seems worthwhile, then, to consider community engagement as it relates to colonialism, postcoloniality, and indigenous archaeology.

Archaeology as a modern enterprise has been intimately linked with colonialism, with archaeologists from the metropole excavating sites located in nations in "the periphery." Like anthropology and many other scientific enterprises, archaeology served, whether deliberately or unintentionally, to provide ideological support for the domination of some nations by others (for a summary, see Lydon and Rizvi 2010). At times, this purpose could be served by the reification of social-evolutionary schema or the treatment of descendant groups as timeless and static, suitable analogues for archaeological data. Or the colonialist stance may even have

acted to *dis*engage or alienate contemporary communities from the archaeological sites occupied by their ancestors or other predecessors, as is especially common when the story of an ancient civilization ends in "collapse" or "disappearance." However, the postcolonial critique has begun to influence the practice of archaeology, including archaeologies of community engagement.

Postcolonial archaeologies, like other forms of postcolonial critique, have "a fundamental ethical basis in examining oppression and inequality in the present. . .reconsider[ing] colonialism from the perspective of colonized people and their cultures" (Lydon and Rizvi 2010: 19). To the extent that community-engaged archaeology seeks to work "for" and "with," not "on" and "in," contemporary communities, there are significant parallels between the postcolonial and engagement agendas. While modern states with prior histories of colonial occupation and/or colonialist archaeology have in many cases managed to curtail the wholesale removal and exploitation of their archaeological patrimony by foreign researchers, new structures have not necessarily meant *local* community control or oversight. And indeed, much of the population may be as alienated as ever from the process of archaeology and the resulting discoveries (see examples described in Eze-Uzomaka 2000; Moser et al. 2002; Atalay 2007 or Chirikure et al. 2010).

Through sustained and vigorous effort, many indigenous groups the world over have gained authority over the sites occupied by their ancestors. Many of the strategies and concepts that undergird community engagement in archaeology have their roots in indigenous archaeology (Atalay 2007). The promulgation of ethical standards has certainly done much to persuade archaeologists of the legitimacy of indigenous claims to archaeological sites, artifacts, and ancestral remains. The World Archaeological Congress's First Code of Ethics asserts, among other points, "that the indigenous cultural heritage rightfully belongs to the indigenous descendants of that heritage" and urges archaeologists to "establish equitable partnerships and relationships between Members and indigenous peoples whose cultural heritage is being investigated" (World Archaeological Congress 1990). However, such appeals may have been ignored if it were not for laws mandating engagement with indigenous communities. NAGPRA – a US law – has already been mentioned above. In Australia, a federal law, the *Aboriginal and Torres Strait Islander Heritage Protection Amendment Act* (1987), picks up where a variety of state laws, such as the *Heritage Conservation Act* (1991) of the Northern Territory, leave off (see Colley 2002).

Evolving circumstances within settler societies – like the USA and Australia – as well as between former colonizers and former colonies, have compelled many archaeologists from the global North to engage with communities at home and abroad. Similar efforts are underway among professionals around the world who recognize the importance of connecting with communities formerly alienated from archaeological research. Pamela Eze-Uzomaka notes, for example, that even a strategy as straightforward as using radio, newspapers, or television to inform people about archaeological discoveries and goals has been ineffective in Nigeria. Scholars from elsewhere in Africa suggest that the question is one of bringing community and scholar interests into alignment, as with some programs that have as a primary goal consultation and empowerment but also include poverty alleviation through employment or tourism (see Eze-Uzomaka 2000: 35; Chirikure et al. 2010).

Ajay Pratap observes that there is still an urban and majoritarian bias to history (and by extension, archaeology) in India. He describes tribal exhibits in museums that treat these people as a part of the nation's timeless "natural" history.

> The fact that the past of ethnic minorities, particularly tribes, is usually neglected, even sixty years after independence is not a very pleasing scenario. . .[It] is a serious lacuna in our curriculums that needs to be addressed and rectified. In a context when history writing in India is increasingly being identified as an exercise in postcoloniality, how can we possibly justify the deletion of the pasts of ethnic minorities?. (Pratap 2009: 15)

What distinguishes Pratap's perspective from that of his colleagues in the West is that he views this as a problem to be solved using archaeological methods rather than policy.

If one were to characterize the "styles" of community engagement that appear to predominate in a range of international settings, the following patterns seem to emerge (see also Marshall 2002a: 212–4). Within the states that have emerged from the independence movements and revolutions of the twentieth century, "community engagement" is frequently described as necessary in order for archaeology to remain viable in tenuous economic or political environments (e.g., Eze-Uzomaka 2000) or in the face of looting (e.g., Qin 2004: 298). Furthermore, engagement becomes a management concern or a problem of definition – which communities should participate? How does an archaeologist build collaborations with resistant communities (e.g., Chirikure et al. 2010)? In the former colonial centers, "community engagement" often seems to entail community participation not only in establishing goals and research agendas but especially in the actual collection of archaeological data (e.g., Merriman 2004; Smith and Waterton 2009). Meanwhile, within the settler societies, "community engagement" tends to be oriented toward addressing imbalances and ameliorating the social and political hardships of subaltern groups. This tendency is also evident in the projects described by researchers with origins or training in the global North at work in the South (e.g., Green et al. 2003). All of which prompts one to consider to what extent these different international "styles" of community engagement have their roots in the power relationships within and among contemporary societies as well as modern concepts of "self" and "other."

Future Directions

Archaeologists often expect community engagement to bring (positive) change to a community. Sometimes, they expect it to reshape an archaeological project. Recent analyses suggest that community engagement has a transformative effect on the discipline more generally. Certainly, working with stakeholders also has led archaeologists to, for example, take oral history more seriously and consider the significance of nonscientific ways of knowing about the past. Archaeologists must also confront the real-world consequences of their research activities. These are no small matters in and of themselves, but community engagement can reach farther, even, than this.
